## Contents

Foreword ..... 9
Navigating the ocean of Judea Pearl's Books ..... 10
Notational Conventions and Preliminaries ..... 11
0.1 Some abbreviations frequently used throughout this book ..... 11
$0.2 \mathcal{N}(!a)$ ..... 11
0.3 One hot ..... 11
0.4 Special sets ..... 11
0.5 Kronecker delta function ..... 12
0.6 Dirac delta function ..... 12
0.7 Indicator function (aka Truth function) ..... 12
0.8 Majority function ..... 12
0.9 Underlined letters indicate random variables ..... 12
0.10 Probability distributions ..... 13
0.11 Discretization of continuous probability distributions ..... 13
0.12 Samples, i.i.d. variables ..... 13
0.13 Normal Distribution ..... 14
0.14 Uniform Distribution ..... 14
0.15 Sigmoid and logit functions ..... 15
0.16 Expected Value and Variance ..... 15
0.17 Conditional Expected Value ..... 15
0.18 Law of Total Variance ..... 16
0.19 Notation for covariances ..... 17
0.20 Conditional Covariance ..... 17
0.21 Linear regression, Ordinary Least Squares (OLS) ..... 18
0.21.1 LR, assuming $x_{\sigma}$ are non-random ..... 18
0.21.2 LR , assuming $x_{\sigma}$ are random and i.i.d. ..... 21
0.22 Short Summary of Boolean Algebra ..... 23
0.23 Entropy, Kullback-Liebler divergence ..... 23
0.24 Definition of various entropies used in Shannon Information Theory ..... 24
Definition of a Bayesian Network ..... 26
1 ARACNE-structure learning ..... 29
2 Backdoor Adjustment ..... 31
2.1 Examples ..... 32
3 Back Propagation (Automatic Differentiation) ..... 35
3.1 General Theory ..... 35
3.1.1 Jacobians ..... 35
3.1.2 bnets for function composition, forward propagation and back propagation ..... 36
3.2 Application to Neural Networks ..... 37
3.2.1 Absorbing $b_{i}^{\lambda}$ into $w_{i \mid j}$. ..... 37
3.2.2 bnets for function composition, forward propagation and back propagation for NN ..... 39
3.3 General bnets instead of Markov chains induced by layered structure of NNs ..... 42
4 Basic Curve Fitting Using Gradient Descent ..... 43
5 Bell and Clauser-Horne Inequalities in Quantum Mechanics ..... 45
6 Berkson's Paradox ..... 46
7 Binary Decision Diagrams ..... 48
8 Chow-Liu Trees and Tree Augmented Naive Bayes (TAN) ..... 52
8.1 Chow-Liu Trees ..... 52
8.2 Tree Augmented Naive Bayes (TAN) ..... 56
9 Counterfactual Reasoning ..... 58
9.1 The 3 Rungs of Causal AI ..... 58
9.2 Two kinds of intervention operators ..... 58
9.3 Do operator for DEN diagrams ..... 60
9.4 Mediation Analysis ..... 62
10 Decision Trees ..... 66
10.1 Transforming a dtree into a bnet ..... 67
10.2 Structure Learning for Dtrees ..... 69
10.2.1 Information Gain, Gini ..... 69
10.2.2 Pseudo-code ..... 72
11 Difference-in-Differences ..... 74
11.1 John Snow, DID and a cholera transmission pathway ..... 74
11.2 PO analysis ..... 76
11.3 Linear Regression ..... 79
12 Digital Circuits ..... 81
12.1 Mapping any dcircuit to a bnet ..... 82
12.1.1 Option A of Fig, 12.2 ..... 82
12.1.2 Option B of Fig,12.2 ..... 82
13 Do-Calculus ..... 83
13.1 Parent Adjustment ..... 86
13.2 3 Rules of do-calculus ..... 87
13.3 Backdoor Adjustment ..... 88
13.4 Front Door Adjustment ..... 89
14 D-Separation ..... 93
15 Dynamic Bayesian Networks ..... 96
16 Expectation Maximization ..... 98
16.1 The EM algorithm: ..... 99
16.1.1 Motivation ..... 100
16.2 Minorize-Maximize (MM) algorithms ..... 101
16.3 Examples ..... 102
16.3.1 Gaussian mixture ..... 102
16.3.2 Blood Genotypes and Phenotypes ..... 103
16.3.3 Missing Data/Imputation ..... 105
17 Front-door Adjustment ..... 106
17.1 Examples ..... 107
18 Generative Adversarial Networks (GANs) ..... 108
19 Gaussian Nodes with Linear Dependence on Parents ..... 113
20 Hidden Markov Model ..... 116
21 Influence Diagrams \& Utility Nodes ..... 120
22 Instrumental Inequality and beyond ..... 122
22.1 I-inequality ..... 122
22.1.1 I-inequality for binary $\mathrm{z}, \mathrm{d}, \mathrm{y}$ ] ..... 124
22.2 Bounds on Effect of IV on treatment outcome y ..... 125
23 Instrumental Variables ..... 128
$23.1 \delta$ with unnmeasured confounder ..... 128
$23.2 \delta$ (with unmeasured confounder) can be inferred via IV ..... 129
23.3 More general bnets with IVs ..... 131
23.4 Instrumental Inequality ..... 131
24 Junction Tree Algorithm ..... 132
25 Kalman Filter ..... 133
25.1 Problem ..... 134
25.2 Solution ..... 134
26 Linear and Logistic Regression ..... 136
26.1 Generalization to $x$ with multiple components (features) ..... 138
26.2 Alternative $V(b, m)$ for logistic regression ..... 138
27 Linear Deterministic Bnets with External Noise ..... 140
27.1 Example of LDEN diagram ..... 140
27.2 Fully Connected LDEN diagrams ..... 141
27.2.1 Fully connected LDEN diagram with $n x=2$ ..... 142
27.2.2 Fully connected LDEN diagram with $n x=3$ ..... 142
27.2.3 Fully connected LDEN diagram with arbitrary $n x$ ..... 143
27.3 Non-linear DEN diagrams ..... 145
28 Markov Blankets ..... 146
29 Markov Chain Monte Carlo (MCMC) ..... 148
29.1 Inverse Cumulative Sampling ..... 148
29.2 Rejection Sampling ..... 150
29.3 Metropolis-Hastings Sampling ..... 151
29.4 Gibbs Sampling ..... 154
29.5 Importance Sampling ..... 155
30 Markov Chains ..... 157
31 Message Passing (Belief Propagation) ..... 158
31.1 Distributed Soldier Counting ..... 158
31.2 Spring Systems ..... 160
31.3 BP for Markov Chains ..... 160
31.4 BP Algorithm for Polytrees ..... 167
31.4.1 How BP algo for polytrees reduces to the BP algo for Markov chains ..... 171
31.5 Derivation of BP Algorithm for Polytrees ..... 172
31.6 Example of BP algo for a Tree ..... 175
31.7 Bipartite bnets ..... 179
31.8 BP for bipartite bnets (BP-BB) ..... 182
31.8.1 BP-BB and general BP agree on Markov chains ..... 183
31.8.2 BP-BB and general BP agree on tree bnets. ..... 185
31.9 BP-BB and sum-product decomposition ..... 187
32 Missing Data, Imputation ..... 188
32.1 Imputation via EM ..... 189
32.2 Imputation via MCMC ..... 192
32.3 Multiple Imputations ..... 193
33 Monty Hall Problem ..... 194
34 Naive Bayes ..... 196
35 Neural Networks ..... 197
35.1 Activation Functions $\mathcal{A}_{i}^{\lambda}: \mathbb{R} \rightarrow \mathbb{R}$ ..... 198
35.2 Weight optimization via supervised training and gradient descent ..... 200
35.3 Non-dense layers ..... 202
35.4 Autoencoder NN ..... 203
36 Noisy-OR gate ..... 204
36.13 ways to interpret the parameters $\pi_{i}$ ..... 205
37 Non-negative Matrix Factorization ..... 208
37.1 Bnet interpretation ..... 208
37.2 Simplest recursive algorithm ..... 209
38 Observational Equivalence of DAGs ..... 210
38.1 Examples ..... 211
39 Potential Outcomes ..... 214
$39.1 G$ and $G_{d e n}$, bnets, the starting point bnets ..... 215
$39.2 G_{\text {do+ }}$ bnet ..... 217
$39.3 G_{i m+}$ bnet ..... 218
39.4 $G_{i m+}$ bnet with nodes $y^{\sigma}(0), y^{\sigma}(1)$ added to it. ..... 219
39.5 Conditional Independence Assumption ..... 221
$39.6 \mathcal{Y}_{\mid \tilde{d}, x}$ and $G_{d o}$ ..... 222
39.7 Translation Dictionary ..... 223
$39.8 \mathcal{Y}_{d \mid \tilde{d}}$ differences (aka treatment effects) ..... 223
39.9 Zero ACE, $\mathcal{Y}_{1 \mid 0}=\mathcal{Y}_{1}$ ..... 225
39.10(SDO, ATE) space ..... 226
39.11Matching Strata ..... 228
39.11.1 Exact strata-match ..... 228
Example, calculation of estimators for a treatment ..... 230
39.11.2 Approximate strata-match ..... 232
39.11.3 Positivity ..... 232
39.12Propensity Score ..... 233
39.13Multi-time PO bnets (Panel Data) ..... 235
40 Program evaluation and review technique (PERT) ..... 238
40.1 Example ..... 240
41 Recurrent Neural Networks ..... 244
41.1 Language Sequence Modeling ..... 247
41.2 Other types of RNN ..... 248
41.2.1 Long Short Term Memory (LSTM) unit (1997) ..... 249
41.2.2 Gated Recurrence Unit (GRU) (2014) ..... 251
42 Regression Discontinuity Design ..... 253
42.1 PO analysis ..... 253
42.2 Linear Regression ..... 254
43 Reinforcement Learning (RL) ..... 256
43.1 Exact RL bnet ..... 259
43.2 Actor-Critic RL bnet ..... 261
43.3 Q function learning RL bnet ..... 263
44 Reliability Box Diagrams and Fault Tree Diagrams ..... 265
44.1 Minimal Cut Sets ..... 271
45 Restricted Boltzmann Machines ..... 273
46 ROC curves ..... 275
47 Scoring the Nodes of a Learned Bnet ..... 278
47.1 Probability Distributions and Special Functions ..... 279
47.2 Single node with no parents ..... 281
47.3 Multiple nodes with any number of parents ..... 283
47.4 Bayesian Scores ..... 285
47.5 Information Theoretic scores ..... 285
48 Simpson's Paradox ..... 287
48.1 Pearl Causality ..... 289
48.2 Numerical Example ..... 290
49 Structure and Parameter Learning for Bnets ..... 291
49.1 Overview ..... 291
49.2 Score based SL algorithms ..... 293
49.3 Constraint based SL algorithms ..... 294
49.4 Pseudo-code for some bnet learning algorithms ..... 295
50 Synthetic Controls ..... 297
50.1 A bnet $G_{t}$ with weighted treatment outcomes ..... 299
50.2 PO analysis ..... 300
51 Transportability: COMING SOON ..... 302
52 Turbo Codes ..... 304
52.1 Decoding Algorithm ..... 307
52.2 Message Passing Interpretation of Decoding Algorithm ..... 309
53 Uplift Modelling ..... 310
53.1 UP types ..... 310
53.2 Some Relevant Technical Facts from Chapter 39 ..... 312
53.3 UP Analysis ..... 312
53.4 UP Decision Trees ..... 314
53.4.1 Appendix, connection between $\Delta_{c}$ and $\Delta_{c \mid j}$ ..... 319
54 Variational Bayesian Approximation ..... 320
54.1 Free Energy $\mathcal{F}(\vec{x})$ ..... 322
55 Zero Information Transmission (Graphoid Axioms) ..... 325
55.1 Consequences of Eq. (55.2)] ..... 325
Bibliography ..... 328

## Foreword

Welcome to Bayesuvius! a proto-book uploaded to github.
A different Bayesian network is discussed in each chapter. Each chapter title is the name of a B net. Chapter titles are in alphabetical order.

This is a volcano in its early stages. First version uploaded to a github repo called Bayesuvius on June 24, 2020. First version only covers 2 B nets (Linear Regression and GAN). I will add more chapters periodically. Remember, this is a moonlighting effort so I can't do it all at once.

For any questions about notation, please go to Notational Conventions section. Requests and advice are welcomed.

Thanks for reading this
Robert R. Tucci

## Navigating the ocean of Judea Pearl's Books

Many of the greatest ideas in the bnet field were invented by Judea Pearl and his collaborators. Thus, this book is heavily indebted to those great scientists. Those ideas have had no clearer and more generous expositor than Judea Pearl himself.

Pearl has written 4 books that I have used in writing Bayesuvius. His 1988 book Ref. [25] dates back to his pre-causal period. That book I used to learn about topics such as d-separation, belief propagation, Markov-blankets, and noisy-ORs. 3 other books that he wrote later, in his causal period, are:

1. In 2000 (1st ed.), and 2013 (2nd ed.), Pearl published what is so far his most technical and exhaustive book on the subject of causality, Ref.[26].
2. In 2016, he released together with Glymour and Jewell, a less advanced "primer" on causality, Ref.[29].
3. In 2018, he released together with Mackenzie his lovely "The Book of Why", Ref. 30 .

Those 3 books I used to learn about causality topics such as do-calculus, backdoor and front-door adjustments, linear deterministic bnets with exogenous noise, and counterfactuals.

## Notational Conventions and Preliminaries

### 0.1 Some abbreviations frequently used throughout this book

- bnet $=\mathrm{B}$ net $=$ Bayesian Network
- $\mathrm{CPT}=$ Conditional Probabilities Table, same as TPM
- DAG = Directed Acyclic Graph
- i.i.d. $=$ independent identically distributed.
- $\mathrm{RCT}=$ Randomized Controlled Trial, aka A/B testing.
- $\mathrm{TPM}=$ Transition Probability Matrix, same as CPT

## $0.2 \mathcal{N}(!a)$

$\mathcal{N}(!a)$ will denote a normalization constant that does not depend on $a$. For example, $P(x)=\mathcal{N}(!x) e^{-x}$ where $\int_{0}^{\infty} d x P(x)=1$.

### 0.3 One hot

A one hot vector of zeros and ones is a vector with all entries zero with the exception of a single entry which is one. A one cold vector has all entries equal to one with the exception of a single entry which is zero. For example, if $x^{n}=\left(x_{0}, x_{1}, \ldots, x_{n-1}\right)$ and $x_{i}=\delta(i, 0)$ then $x^{n}$ is one hot.

### 0.4 Special sets

Define $\mathbb{Z}, \mathbb{R}, \mathbb{C}$ to be the integers, real numbers and complex numbers, respectively.

For $a<b$, define $I_{\mathbb{Z}}$ to be the integers in the interval $I$, where $I=[a, b],[a, b),(a, b],(a, b)$ (i.e, $I$ can be closed or open on either side).
$A_{>0}=\{k \in A: k>0\}$ for $A=\mathbb{Z}, \mathbb{R}$.

### 0.5 Kronecker delta function

For $x, y$ in discrete set $S$,

$$
\delta(x, y)=\left\{\begin{array}{l}
1 \text { if } x=y  \tag{1}\\
0 \text { if } x \neq y
\end{array}\right.
$$

### 0.6 Dirac delta function

For $x, y \in \mathbb{R}$,

$$
\begin{equation*}
\int_{-\infty}^{+\infty} d x \delta(x-y) f(x)=f(y) \tag{2}
\end{equation*}
$$

### 0.7 Indicator function (aka Truth function)

$$
\mathbb{1}(\mathcal{S})=\left\{\begin{array}{l}
1 \text { if } \mathcal{S} \text { is true }  \tag{3}\\
0 \text { if } \mathcal{S} \text { is false }
\end{array}\right.
$$

For example, $\delta(x, y)=\mathbb{1}(x=y)$.

### 0.8 Majority function

The majority function is defined as follows.

$$
\operatorname{majority}(L)=\underset{\text { (ties resolved by chance) }}{\text { most common element of list } L}
$$

Note that the majority function acts on lists, not sets. By definition, all elements of a set appear only once in the set. majority $(L)$ is usually used when the elements of $L$ are categorical (i.e., not real numbers). When they are real numbers, it makes more sense to use, instead of majority $(L)$, a simple average of the elements of $L$.

### 0.9 Underlined letters indicate random variables

Random variables will be indicated by underlined letters and their values by nonunderlined letters. Each node of a bnet will be labelled by a random variable. Thus, $\underline{x}=x$ means that node $\underline{x}$ is in state $x$.

It is more conventional to use an upper case letter to indicate a random variable and a lower case letter for its state. Thus, $X=x$ means that random variable $X$ is
in state $x$. However, we have opted in this book to avoid that notation, because we often want to define certain lower case letters to be random variables or, conversely, define certain upper case letters to be non-random variables.

### 0.10 Probability distributions

$P_{\underline{x}}(x)=P(\underline{x}=x)=P(x)$ is the probability that random variable $\underline{x}$ equals $x \in S_{\underline{x}}$. $S_{\underline{x}}$ is the set of states (i.e., values) that $\underline{x}$ can assume and $n_{\underline{x}}=\left|S_{\underline{x}}\right|$ is the size (aka cardinality) of that set. Hence,

$$
\begin{equation*}
\sum_{x \in S_{\underline{x}}} P_{\underline{x}}(x)=1 \tag{5}
\end{equation*}
$$

$$
\begin{gather*}
P_{\underline{x}, \underline{y}}(x, y)=P(\underline{x}=x, \underline{y}=y)=P(x, y)  \tag{6}\\
P_{\underline{x} \mid \underline{y}}(x \mid y)=P(\underline{x}=x \mid \underline{y}=y)=P(x \mid y)=\frac{P(x, y)}{P(y)} \tag{7}
\end{gather*}
$$

### 0.11 Discretization of continuous probability distributions

The TPM of a node of a bnet can be either a discrete or a continuous probability distribution. To go from continuous to discrete, one replaces integrals over states of a node by sums over new states, and Dirac delta functions by Kronecker delta functions. More precisely, consider a function $f:[a, b] \rightarrow \mathbb{R}$. Express $[a, b]$ as a union of small, disjoint (except for one point) closed sub-intervals (bins) of length $\Delta x$. Name one point in each bin to be the representative of that bin, and let $S_{\underline{x}}$ be the set of all the bin representatives. This is called discretization or binning. Then

$$
\begin{equation*}
\frac{1}{(b-a)} \int_{[a, b]} d x f(x) \rightarrow \frac{\Delta x}{(b-a)} \sum_{x \in S_{\underline{x}}} f(x)=\frac{1}{n_{\underline{x}}} \sum_{x \in S_{\underline{x}}} f(x) . \tag{8}
\end{equation*}
$$

Both sides of last equation are 1 when $f(x)=1$. Furthermore, if $y \in S_{\underline{x}}$, then

$$
\begin{equation*}
\int_{[a, b]} d x \delta(x-y) f(x)=f(y) \rightarrow \sum_{x \in S_{\underline{\underline{x}}}} \delta(x, y) f(x)=f(y) . \tag{9}
\end{equation*}
$$

### 0.12 Samples, i.i.d. variables

$$
\begin{equation*}
\vec{x}=(x[0], x[1], x[2] \ldots, x[\operatorname{nsam}(\vec{x})-1])=x[:] \tag{10}
\end{equation*}
$$

$\operatorname{nsam}(\vec{x})$ is the number of samples of $\vec{x} . \underline{x}[\sigma] \in S_{\underline{x}}$ are i.i.d. (independent identically distributed) samples with

$$
\begin{gather*}
\left.x[\sigma] \sim P_{\underline{x}} \text { (i.e. } P_{\underline{x[\sigma]}}=P_{\underline{x}}\right)  \tag{11}\\
P(\underline{x}=x)=\frac{1}{n \operatorname{sam}(\vec{x})} \sum_{\sigma} \mathbb{1}(x[\sigma]=x) \tag{12}
\end{gather*}
$$

Hence, for any $f: S_{\underline{x}} \rightarrow \mathbb{R}$,

$$
\begin{equation*}
\sum_{x} P(\underline{x}=x) f(x)=\frac{1}{n \operatorname{sam}(\vec{x})} \sum_{\sigma} f(x[\sigma]) \tag{13}
\end{equation*}
$$

If we use two sampled variables, say $\vec{x}$ and $\vec{y}$, in a given bnet, their number of samples $n \operatorname{sam}(\vec{x})$ and $n \operatorname{sam}(\vec{y})$ need not be equal.

$$
\begin{gather*}
P(\vec{x})=\prod_{\sigma} P(x[\sigma])  \tag{14}\\
\sum_{\vec{x}}=\prod_{\sigma} \sum_{x[\sigma]}  \tag{15}\\
\partial_{\vec{x}}=\left[\partial_{x[0]}, \partial_{x[1]}, \partial_{x[2]}, \ldots, \partial_{x[n \operatorname{sam}(\vec{x})-1]}\right]  \tag{16}\\
P(\vec{x}) \approx\left[\prod_{x} P(x)^{P(x)}\right]_{\operatorname{nsam}(\vec{x})}  \tag{17}\\
=e^{\operatorname{nsam}(\vec{x}) \sum_{x} P(x) \ln P(x)}  \tag{18}\\
=e^{-n \operatorname{sam}(\vec{x}) H\left(P_{\underline{x}}\right)} \tag{19}
\end{gather*}
$$

### 0.13 Normal Distribution

For $x, \mu, \sigma \in \mathbb{R}, \sigma>0$

$$
\begin{equation*}
\mathcal{N}\left(x ; \mu, \sigma^{2}\right)=\frac{1}{\sigma \sqrt{2 \pi}} e^{-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^{2}} \tag{20}
\end{equation*}
$$

### 0.14 Uniform Distribution

For $a<b, x \in[a, b]$

$$
\begin{equation*}
\mathcal{U}(x ; a, b)=\frac{1}{b-a} \tag{21}
\end{equation*}
$$

### 0.15 Sigmoid and logit functions

The sigmoid function sig: $\mathbb{R} \rightarrow[0,1]$ is defined by

$$
\begin{equation*}
\operatorname{sig}(x)=\frac{1}{1+e^{-x}} \tag{22}
\end{equation*}
$$

$\operatorname{sig}()$ is monotonically increasing with $\operatorname{sig}(-\infty)=0$ and $\operatorname{sig}(+\infty)=1$.
The logit or log-odds function logit: $[0,1] \rightarrow \mathbb{R}$ is defined by

$$
\begin{equation*}
\operatorname{logit}(p)=\ln \frac{p}{1-p} \tag{23}
\end{equation*}
$$

$\operatorname{logit}()$ is the inverse of $\operatorname{sig}()$ :

$$
\begin{equation*}
\operatorname{logit}[\operatorname{sig}(x)]=x \tag{24}
\end{equation*}
$$

### 0.16 Expected Value and Variance

Given a random variable $\underline{x}$ with states $S_{\underline{x}}$ and a function $f: S_{\underline{x}} \rightarrow \mathbb{R}$, define

$$
\begin{gather*}
E_{\underline{x}}[f(\underline{x})]=E_{x \sim P(x)}[f(x)]=\sum_{x} P(x) f(x)  \tag{25}\\
\begin{aligned}
\operatorname{Var}_{\underline{x}}[f(\underline{x})]=E_{\underline{x}}\left[\left(f(\underline{x})-E_{\underline{x}}[f(\underline{x})]\right)^{2}\right] \\
=E_{\underline{x}}\left[f(\underline{x})^{2}\right]-\left(E_{\underline{x}}[f(\underline{x})]\right)^{2} \\
E[\underline{x}]=E_{\underline{x}}[\underline{x}] \\
\operatorname{Var}[\underline{x}]=\operatorname{Var}_{\underline{x}}[\underline{x}]
\end{aligned} \tag{26}
\end{gather*}
$$

### 0.17 Conditional Expected Value

Given a random variable $\underline{x}$ with states $S_{\underline{x}}$, a random variable $\underline{y}$ with states $S_{\underline{y}}$, and a function $f: S_{\underline{x}} \times S_{\underline{y}} \rightarrow \mathbb{R}$, define

$$
\begin{gather*}
E_{\underline{x} \mid \underline{y}}[f(\underline{x}, \underline{y})]=\sum_{x} P(x \mid \underline{y}) f(x, \underline{y}),  \tag{30}\\
E_{\underline{x} \mid \underline{y}=y}[f(\underline{x}, y)]=E_{\underline{x} \mid y}[f(\underline{x}, y)]=\sum_{x} P(x \mid y) f(x, y) . \tag{31}
\end{gather*}
$$

Note that

$$
\begin{align*}
E_{\underline{y}}\left[E_{\underline{x} \mid \underline{y}}[f(\underline{x}, \underline{y})]\right] & =\sum_{x, y} P(x \mid y) P(y) f(x, y)  \tag{32}\\
& =\sum_{x, y} P(x, y) f(x, y)  \tag{33}\\
& =E_{\underline{x}, \underline{y}}[f(\underline{x}, \underline{y})] . \tag{34}
\end{align*}
$$

### 0.18 Law of Total Variance

Claim 1 Suppose $P: S_{\underline{x}} \times S_{y} \rightarrow[0,1]$ is a probability distribution. Suppose $f$ : $S_{\underline{x}} \times S_{\underline{y}} \rightarrow \mathbb{R}$ and $f=f(x, y)$. Then

$$
\begin{equation*}
\operatorname{Var}_{\underline{x}, \underline{y}}(f)=E_{\underline{y}}\left[\operatorname{Var}_{\underline{x} \mid \underline{y}}(f)\right]+\operatorname{Var}_{\underline{y}}\left(E_{\underline{x} \mid \underline{y}}[f]\right) . \tag{35}
\end{equation*}
$$

In particular,

$$
\begin{equation*}
\operatorname{Var}_{\underline{x}}(x)=E_{\underline{y}}\left[\operatorname{Var}_{\underline{x} \mid \underline{y}}(x)\right]+\operatorname{Var}_{\underline{y}}\left(E_{\underline{x} \mid \underline{y}}[x]\right) . \tag{36}
\end{equation*}
$$

proof:
Let

$$
\begin{equation*}
A=\sum_{y} P(y)\left(\sum_{x} P(x \mid y) f\right)^{2} \tag{37}
\end{equation*}
$$

Then

$$
\begin{gather*}
\operatorname{Var}_{\underline{x}, \underline{y}}(f)=\sum_{x, y} P(x, y) f^{2}-\left(\sum_{x, y} P(x, y) f\right)^{2}  \tag{38}\\
=\left\{\begin{array}{l}
\sum_{x, y} P(x, y) f^{2}-A \\
+\left(A-\left(\sum_{x, y} P(x, y) f\right)^{2}\right) \\
E_{\underline{y}}\left[\operatorname{Var}_{\underline{x} \mid \underline{y}}(f)\right]=\sum_{y} P(y)\left(\sum_{x} P(x \mid y) f^{2}-\left(\sum_{x} P(x \mid y) f\right)^{2}\right) \\
=\sum_{x, y} P(x, y) f^{2}-A
\end{array}\right.  \tag{39}\\
\operatorname{Var}_{\underline{y}}\left(E_{\underline{x} \mid \underline{y}}[f]\right)=\sum_{y} P(y)\left(\sum_{x} P(x \mid y) f\right)^{2}-\left(\sum_{y} P(y) \sum_{x} P(x \mid y) f\right)^{2}  \tag{40}\\
=A-\left(\sum_{x, y} P(x, y) f\right)^{2} \tag{41}
\end{gather*}
$$

## QED

### 0.19 Notation for covariances

Consider two random variables $\underline{x}, \underline{y}$.

- Mean value of $\underline{x}$

$$
\begin{equation*}
\langle\underline{x}\rangle=E_{\underline{x}}[\underline{x}] \tag{44}
\end{equation*}
$$

- Signed distance of $\underline{x}$ to its mean value

$$
\begin{equation*}
\Delta \underline{x}=\underline{x}-\langle\underline{x}\rangle \tag{45}
\end{equation*}
$$

- Covariance of $(\underline{x}, \underline{y})$

$$
\begin{equation*}
\operatorname{Cov}(\underline{x}, \underline{y})=\langle\underline{x}, \underline{y}\rangle=\langle\Delta \underline{x} \Delta \underline{y}\rangle=\langle\underline{x} \underline{y}\rangle-\langle\underline{x}\rangle\langle\underline{y}\rangle \tag{46}
\end{equation*}
$$

$\langle\underline{x}, \underline{y}\rangle$ is symmetric (i.e., $\langle\underline{x}, \underline{y}\rangle=\langle\underline{y}, \underline{x}\rangle$ ) and bilinear (i.e., $\left\langle\sum_{i} \alpha_{i} \underline{x}_{i}, \underline{y}\right\rangle=$ $\sum_{i} \alpha_{i}\left\langle\underline{x}_{i}, \underline{y}\right\rangle$, where $\alpha_{i} \in \mathbb{R}$ are non-random scalars and $\underline{x}_{i}, \underline{y} \in \mathbb{R}$ are realvalued random variables.)

- Variance of $\underline{x}$

$$
\begin{equation*}
\operatorname{Var}(\underline{x})=\langle\underline{x}, \underline{x}\rangle \tag{47}
\end{equation*}
$$

- Standard deviation or $\underline{x}$

$$
\begin{equation*}
\sigma_{\underline{x}}=\sqrt{\langle\underline{x}, \underline{x}\rangle} \tag{48}
\end{equation*}
$$

- Correlation Coefficient of $(\underline{x}, \underline{y})$

$$
\begin{equation*}
\rho_{\underline{x}, \underline{y}}=\frac{\langle\underline{x}, \underline{y}\rangle}{\sqrt{\langle\underline{x}, \underline{x}\rangle\langle\underline{y}, \underline{y}\rangle}} \tag{49}
\end{equation*}
$$

### 0.20 Conditional Covariance

Let $\underline{x}, \underline{y}, \underline{a}$ be random variables. The covariance $\operatorname{Cov}(\underline{x}, \underline{y} \mid \underline{a})$ of $\underline{x}$ and $\underline{y}$ given $\underline{a}$, is defined the same way as $\operatorname{Cov}(\underline{x}, \underline{y})$, except that all expected values are conditioned on $\underline{a}$.

$$
\begin{equation*}
\operatorname{Cov}(\underline{x}, \underline{y} \mid \underline{a})=\langle\underline{x}, \underline{y}\rangle_{\mid \underline{a}}=\left\langle\left(\underline{x}-\langle\underline{x}\rangle_{\mid \underline{a}}\right)\left(\underline{y}-\langle\underline{y}\rangle_{\mid \underline{a}}\right)\right\rangle_{\mid \underline{a}} \tag{50}
\end{equation*}
$$

where

$$
\begin{equation*}
\langle\underline{x}\rangle_{\mid \underline{a}}=E_{\underline{x} \mid \underline{a}}[\underline{x}] . \tag{51}
\end{equation*}
$$

### 0.21 Linear regression, Ordinary Least Squares (OLS)

Wikipedia articles

1. Linear Regression (LR)

- linear regression, Ref. 64]
- simple linear regression, Ref. 79]
- errors in variable, Ref. 51]

2. Least squares (LS)

- least squares, Ref. 63]
- ordinary least squares (OLS), Ref. [75]

In LR, the dependent variables $y$ equal a linear combination of some independent variables $x$ plus some external noise variables $\epsilon$ called the residuals.

Below, we consider two types of LR:

1. LR in which the independent variables are non-random.
2. LR in which the independent variables are random and i.i.d.

Once one assumes that certain variables are random, a "model" (i.e., a bnet) for the random variables must be specified.

For LR of type 2 , there is randomness in $y$ coming from the randomness in $x$ and in the residuals. For LR of type 1, there is randomness in $y$ too, but it comes from the residuals only.

OLS provides a cost function which when minimized, yields LR. The term OLS is often used to refer to LR of type 1.

### 0.21.1 LR, assuming $x_{\sigma}$ are non-random

Let
$\sigma \in\{0,1,2, \ldots$, nsam -1$\}$ : sample index
$y_{\sigma} \in \mathbb{R}$ : dependent variables
$x_{\sigma j} \in \mathbb{R}$ : independent variables
$\epsilon_{\sigma} \in \mathbb{R}$ : residuals
$\beta_{0}, \beta_{j} \in \mathbb{R}$ : regression coefficients

$$
\begin{equation*}
y_{\sigma}=\beta_{0}+\sum_{j=1}^{n} x_{\sigma j} \beta_{j}+\epsilon_{\sigma} \tag{52}
\end{equation*}
$$

If we define

$$
\begin{equation*}
x_{\sigma 0}=1 \tag{53}
\end{equation*}
$$

for all $\sigma$, then

$$
\begin{equation*}
y_{\sigma}=\sum_{j=0}^{n} x_{\sigma j} \beta_{j}+\epsilon_{\sigma} \tag{54}
\end{equation*}
$$

If $y$ and $\epsilon$ are $n s a m \times 1$ column vectors and $\beta$ is an $(n+1) \times 1$ column vector, then can write previous equation in matrix form as:

$$
\begin{equation*}
y=X \beta+\epsilon \tag{55}
\end{equation*}
$$

Define the projection matrices

$$
\begin{equation*}
\wedge=X\left(X^{T} X\right)^{-1} X^{T}, \quad \vee=1-\wedge \tag{56}
\end{equation*}
$$

A square matrix $M$ is symmetric if $M^{T}=M$ and is idempotent if $M^{2}=M . \wedge$ is symmetric and idempotent and so is $\vee$. Note that $\wedge$ and $\vee$ also satisfy:

$$
\begin{equation*}
\vee \wedge=\wedge \vee=0 \tag{57}
\end{equation*}
$$

and

$$
\begin{equation*}
\wedge X=X, \quad \vee X=0 \tag{58}
\end{equation*}
$$

One has

$$
\begin{equation*}
\beta=\left(X^{T} X\right)^{-1} X^{T}(y-\epsilon) . \tag{59}
\end{equation*}
$$

Define

$$
\begin{gather*}
\hat{\beta}=\left(X^{T} X\right)^{-1} X^{T} y=B y  \tag{60a}\\
\hat{y}=X \hat{\beta}=\wedge y \tag{60b}
\end{gather*}
$$

and

$$
\begin{equation*}
\hat{\epsilon}=y-X \hat{\beta}=y-\hat{y}=(1-\wedge) y=\vee y . \tag{60c}
\end{equation*}
$$

$\wedge$ is sometimes called the hat matrix, because it gives $y$ a hat.
Given any function $f=f(y, X, \epsilon)$ and a scalar factor $\xi \in \mathbb{R}$, suppose $f(\xi y, \xi X, \xi \epsilon)=$ $\xi^{\mathcal{O}} f(y, X, \epsilon)$. Then we will say that $f(\cdot)$ is of order $\mathcal{O}$ under scaling. Note that $\{X, y, \hat{y}, \epsilon, \hat{\epsilon}\}$ are all of order 1 under scaling, $\{\beta, \hat{\beta}, \wedge, \vee\}$ are all of order 0 under scaling, and $B$ is of order -1 under scaling. Thus, the estimator variables (i.e, those with a hat) scale the same way as the variables without a hat that they are estimating. Furthermore, $\beta$, its estimator $\hat{\beta}$, and the projection matrices $\wedge, \vee$ are invariant $(\mathcal{O}=0)$ under scaling.

Fig 3 illustrates that $y$ can be expressed as a sum of 2 estimators:

$$
\begin{equation*}
y=\underbrace{\hat{y}}_{\wedge y}+\underbrace{\hat{\epsilon}}_{\vee y} . \tag{61}
\end{equation*}
$$

Figure 3: Decomposition of $y$ into sum of two estimators, $\hat{y}$ and $\hat{\epsilon}$.
model dependent results:
Assume the components of $\epsilon$ are random over $\sigma$ and

$$
\begin{equation*}
E_{\sigma}[\underline{\epsilon}]=\langle\underline{\epsilon}\rangle=0 \tag{62}
\end{equation*}
$$

Assume $X$ and $\beta$ are not random. This makes $\underline{y}=X \beta+\underline{\epsilon}$ and $\underline{\hat{\beta}}=\left(X^{T} X\right)^{-1} X^{T} \underline{y}$ random. One finds that

$$
\begin{gather*}
\langle\underline{y}\rangle=X \beta  \tag{63}\\
\langle\underline{\hat{y}}\rangle=\wedge\langle\underline{y}\rangle=\langle\underline{y}\rangle  \tag{64a}\\
\langle\underline{\hat{e}}\rangle=\vee\langle\underline{y}\rangle=0  \tag{64b}\\
\langle\underline{\hat{\beta}}\rangle=\beta \tag{64c}
\end{gather*}
$$

So far, we have assumed a zero mean value for $\epsilon$. Next, assume "homoscedasticity" (HS), which means that

$$
\begin{equation*}
\left\langle\underline{\epsilon}, \underline{\epsilon}^{T}\right\rangle=\xi^{2} I_{n s a m} \tag{64d}
\end{equation*}
$$

where $\xi \geq 0$, nsam $=\sum_{\sigma}$ and $I_{\text {nsam }}$ is the $n s a m \times n s a m$ identity matrix. It follows that

$$
\begin{align*}
& \left\langle\underline{y}, \underline{y}^{T}\right\rangle=\left\langle\underline{\epsilon}, \underline{\epsilon}^{T}\right\rangle=\xi^{2} I_{n s a m}  \tag{65}\\
& \left\langle\underline{\hat{\epsilon}}, \hat{\epsilon}^{T}\right\rangle=\vee\left\langle\underline{y}, \underline{y}^{T}\right\rangle \vee^{T}=\xi^{2} \vee \tag{66}
\end{align*}
$$

$$
\begin{equation*}
\left\langle\underline{\hat{y}}, \underline{\hat{y}}^{T}\right\rangle=\wedge\left\langle\underline{y}, \underline{y}^{T}\right\rangle \wedge^{T}=\xi^{2} \wedge \tag{67}
\end{equation*}
$$

and

$$
\begin{equation*}
\left\langle\underline{\hat{\beta}}, \underline{\hat{\beta}}^{T}\right\rangle=B\left\langle\underline{y}, \underline{y}^{T}\right\rangle B^{T}=\xi^{2}\left(X^{T} X\right)^{-1} . \tag{68}
\end{equation*}
$$

The goodness of fit for this model is often measured using the coefficient of determination $R^{2}$. $R^{2}$ is defined by

$$
\begin{equation*}
R^{2}=\frac{\|\underline{\hat{y}}-\langle\underline{\hat{y}}\rangle\|^{2}}{\|\underline{y}-\langle\underline{y}\rangle\|^{2}}=\frac{\operatorname{tr}\left\langle\underline{\hat{y}}, \underline{\hat{y}}^{T}\right\rangle}{\operatorname{tr}\left\langle\underline{y}, \underline{y}^{T}\right\rangle} \tag{69}
\end{equation*}
$$

If HS holds, then $R^{2}$ reduces to

$$
\begin{equation*}
R^{2}=\frac{\operatorname{tr} \wedge}{n s a m} \tag{70}
\end{equation*}
$$

### 0.21.2 LR, assuming $x_{\sigma}$ are random and i.i.d.

Let
$\underline{y} \in \mathbb{R}$ : true value of dependent variable
$\underline{\hat{\hat{y}}} \in \mathbb{R}:$ estimator of dependent variable
$\underline{\epsilon} \in \mathbb{R}$ : residual
$\underline{x}_{j} \in \mathbb{R}$ : independent variables
$\beta_{0}, \beta_{j} \in \mathbb{R}$ : regression coefficients

$$
\begin{gather*}
\underline{\hat{y}}=\beta_{0}+\sum_{j=1}^{n} \beta_{j} \underline{x}_{j}  \tag{71}\\
\underline{y}=\underline{\hat{y}}+\underline{\epsilon} \tag{72}
\end{gather*}
$$

Assume

$$
\begin{equation*}
\langle\underline{\epsilon}\rangle=0 \tag{73}
\end{equation*}
$$

and

$$
\begin{equation*}
\left\langle\underline{x}_{j}, \underline{\epsilon}\right\rangle=0 \tag{74}
\end{equation*}
$$

for all $j$.
For $k=1, \ldots, n$,

$$
\begin{equation*}
\left\langle\underline{x}_{k}, \underline{y}\right\rangle=\sum_{j=1}^{n} \beta_{j}\left\langle\underline{x}_{k}, \underline{x}_{j}\right\rangle . \tag{75}
\end{equation*}
$$

Let $\underline{x}^{n}$ and $\beta^{n}$ be column vectors. Then

$$
\begin{equation*}
\left\langle\underline{x}^{n}, \underline{y}\right\rangle=\left\langle\underline{x}^{n},\left(\underline{x}^{n}\right)^{T}\right\rangle \beta^{n}, \tag{76}
\end{equation*}
$$

$$
\begin{gather*}
\beta^{n}=\left\langle\underline{x}^{n},\left(\underline{x}^{n}\right)^{T}\right\rangle^{-1}\left\langle\underline{x}^{n}, \underline{y}\right\rangle .  \tag{77}\\
\beta_{0}=\langle\underline{y}\rangle-\left(\beta^{n}\right)^{T}\left\langle\underline{x}^{n}\right\rangle \tag{78}
\end{gather*}
$$

Notice that the equations for the regression coefficients are very similar for the two cases of $x_{\sigma}$-nonrandom and $x_{\sigma}$-random. In fact, if we replace bilinears as follows

$$
\begin{gather*}
X^{T} y \longrightarrow\left\langle\underline{x}^{n}, \underline{y}\right\rangle  \tag{79}\\
X^{T} X \longrightarrow\left\langle\underline{x}^{n},\left(\underline{x}^{n}\right)^{T}\right\rangle \tag{80}
\end{gather*}
$$

we go from the estimator of $\beta$ for one case to the estimator of $\beta$ for the other case:

$$
\begin{equation*}
\text { Eq. (60a) } \longrightarrow \text { Eq. } 77 \tag{81}
\end{equation*}
$$

Next, we will write Eq. (77) for the special cases $n=1$ and $n=2$, where $n$ is the number of independent variables $\underline{x}_{j}$

1. $n=1$ ( $\underline{y}$ fitted by a line)

$$
\begin{equation*}
\underline{y}=\beta_{0}+\beta \underline{x}+\underline{\epsilon} \tag{82}
\end{equation*}
$$

Eq. 77 becomes

$$
\begin{equation*}
\beta_{\underline{y}, \underline{x}}=\beta=\frac{\langle\underline{y}, \underline{x}\rangle}{\langle\underline{x}, \underline{x}\rangle} \tag{83}
\end{equation*}
$$

2. $n=2$ ( $\underline{y}$ fitted by a plane $)$

$$
\begin{equation*}
\underline{y}=\beta_{0}+\beta_{1} \underline{x}_{1}+\beta_{2} \underline{x}_{2}+\underline{\epsilon} \tag{84}
\end{equation*}
$$

Define

$$
\begin{equation*}
C_{i, j}=\left\langle\underline{x}_{i}, \underline{x}_{j}\right\rangle \tag{85}
\end{equation*}
$$

for all $i, j$. Then Eq. 77 becomes ${ }^{1}$

$$
\begin{align*}
{\left[\begin{array}{l}
\beta_{1} \\
\beta_{2}
\end{array}\right] } & =C^{-1}\left[\begin{array}{l}
\left\langle\underline{y}, \underline{x}_{1}\right\rangle \\
\left\langle\underline{y}, \underline{x}_{2}\right\rangle
\end{array}\right]  \tag{86}\\
& =\frac{1}{\operatorname{det} C}\left[\begin{array}{cc}
C_{22} & -C_{12} \\
-C_{21} & C_{11}
\end{array}\right]\left[\begin{array}{l}
\left\langle\underline{y}, \underline{x}_{1}\right\rangle \\
\left\langle\underline{y}, \underline{x}_{2}\right\rangle
\end{array}\right] \tag{87}
\end{align*}
$$

${ }^{1}$ Recall that if $M=\left[\begin{array}{ll}a & b \\ c & d\end{array}\right]$ then $M^{-1}=\frac{1}{\operatorname{det} M}\left[\begin{array}{cc}d & -b \\ -c & a\end{array}\right]$

Hence,

$$
\begin{equation*}
\beta_{\underline{y}, \underline{x}_{1} \mid \underline{x}_{2}}=\beta_{1}=\frac{C_{22}\left\langle\underline{y}, \underline{x}_{1}\right\rangle-C_{12}\left\langle\underline{y}, \underline{x}_{2}\right\rangle}{C_{11} C_{12}-C_{12}^{2}} \tag{88}
\end{equation*}
$$

Eq. (88) agrees with the value of $\beta_{Y X \mid Z}$ in Ref. 21] by Pearl, if we replace in Pearl's formulae $X \rightarrow \underline{x}_{1}, Y \rightarrow \underline{y}, Z \rightarrow \underline{x}_{2}$.

### 0.22 Short Summary of Boolean Algebra

See Ref. [46] for more info about this topic.
Suppose $x, y, z \in\{0,1\}$. Define

$$
\begin{gather*}
x \text { or } y=x \vee y=x+y-x y,  \tag{89}\\
x \text { and } y=x \wedge y=x y, \tag{90}
\end{gather*}
$$

and

$$
\begin{equation*}
\text { not } x=\bar{x}=1-x, \tag{91}
\end{equation*}
$$

where we are using normal addition and multiplication on the right hand sides $\cdot{ }^{2}$
Actually, since $x \wedge y=x y$, we can omit writing the symbol $\wedge$. The symbol $\wedge$ is useful to exhibit the symmetry of the identities, and to remark about the analogous identities for sets, where $\wedge$ becomes intersection $\cap$ and $\vee$ becomes union $\cup$. However, for practical calculations, $\wedge$ is an unnecessary nuisance.

Since $x \in\{0,1\}$,

$$
\begin{equation*}
P(\bar{x})=1-P(x) . \tag{92}
\end{equation*}
$$

Clearly, from analyzing the simple event space $(x, y) \in\{0,1\}^{2}$,

$$
\begin{equation*}
P(x \vee y)=P(x)+P(y)-P(x \wedge y) . \tag{93}
\end{equation*}
$$

### 0.23 Entropy, Kullback-Liebler divergence

For probabilty distributions $p(x), q(x)$ of $x \in S_{\underline{x}}$

- Entropy:

$$
\begin{equation*}
H(p)=-\sum_{x} p(x) \ln p(x) \geq 0 \tag{94}
\end{equation*}
$$

- Kullback-Liebler divergence:

$$
\begin{equation*}
D_{K L}(p \| q)=\sum_{x} p(x) \ln \frac{p(x)}{q(x)} \geq 0 \tag{95}
\end{equation*}
$$

[^0]| Associativity | $\begin{aligned} & x \vee(y \vee z)=(x \vee y) \vee z \\ & x \wedge(y \wedge z)=(x \wedge y) \wedge z \end{aligned}$ |
| :---: | :---: |

Table 1: Boolean Algebra Identities

- Cross entropy:

$$
\begin{align*}
C E(p \rightarrow q) & =-\sum_{x} p(x) \ln q(x)  \tag{96}\\
& =H(p)+D_{K L}(p \| q) \tag{97}
\end{align*}
$$

### 0.24 Definition of various entropies used in Shannon Information Theory

- (plain) Entropy of $\underline{x}$

$$
\begin{equation*}
H(\underline{x})=-\sum_{x} P(x) \ln P(x) \tag{98}
\end{equation*}
$$

This quantity measures the spread of $P_{\underline{x}}$.

- Conditional Entropy of $\underline{y}$ given $\underline{x}$

$$
\begin{align*}
H(\underline{y} \mid \underline{x}) & =-\sum_{x, y} P(x, y) \ln P(y \mid x)  \tag{99}\\
& =H(\underline{y}, \underline{x})-H(\underline{x}) \tag{100}
\end{align*}
$$

This quantity measures the conditional spread of $\underline{y}$ given $\underline{x}$.

- Mutual Information (MI) of $\underline{x}$ and $\underline{y}$

$$
\begin{align*}
H(\underline{y}: \underline{x}) & =\sum_{x, y} P(x, y) \ln \frac{P(x, y)}{P(x) P(y)}  \tag{101}\\
& =H(\underline{x})+H(\underline{y})-H(\underline{y}, \underline{x}) \tag{102}
\end{align*}
$$

This quantity measures the correlation between $\underline{x}$ and $\underline{y}$.

- Conditional Mutual Information (CMI) ${ }^{3}$ of $\underline{x}$ and $\underline{y}$ given $\underline{\lambda}$

$$
\begin{align*}
H(\underline{y}: \underline{x} \mid \underline{\lambda}) & =\sum_{x, y, \lambda} P(x, y, \lambda) \ln \frac{P(x, y \mid \lambda)}{P(x \mid \lambda) P(y \mid \lambda)}  \tag{103}\\
& =H(\underline{x} \mid \underline{\lambda})+H(\underline{y} \mid \underline{\lambda})-H(\underline{y}, \underline{x} \mid \underline{\lambda}) \tag{104}
\end{align*}
$$

This quantity measures the conditional correlation of $\underline{x}$ and $\underline{y}$ given $\underline{\lambda}$.

- Kullback-Liebler Divergence from $P_{\underline{x}}$ to $P_{\underline{y}}$.

Assume random variables $\underline{x}$ and $\underline{y}$ have the same set of states $S_{\underline{x}}=S_{\underline{y}}$. Then

$$
\begin{equation*}
D_{K L}\left(P_{\underline{x}} \| P_{\underline{y}}\right)=\sum_{x} P_{\underline{x}}(x) \ln \frac{P_{\underline{x}}(x)}{P_{\underline{y}}(x)} \tag{105}
\end{equation*}
$$

This measures a non-symmetric distance between the probability distributions $P_{\underline{x}}$ and $P_{\underline{y}} . D_{K L}\left(P_{\underline{x}} \| P_{\underline{y}}\right)$ is non-negative and equals zero iff $P_{\underline{x}}=P_{\underline{y}}$.

[^1]
## Definition of a Bayesian Network

A directed graph $G=(V, E)$ consists of two sets, $V$ and $E . V$ contains the vertices (nodes) and $E$ contains the edges (arrows). An arrow $a \rightarrow b$ is an ordered pair $(a, b)$ where $a, b \in V$.

The parents of a node $x$ are those nodes $a$ such that there are arrows $a \rightarrow x$. The children of a node $x$ are those nodes $b$ such that there are arrows $x \rightarrow b$. A root node is a node with no parents. A leaf node is a node with no children. The neighbors of a node $x$ is the set of parents and children of $x$.

A path is a set of nodes that are connected by arrows, so that all nodes have 1 or 2 neighbors, but only two nodes (open path) or zero nodes (closed path) have only one neighbor. A directed path is a path in which all the arrows point in the same direction. A loop is a closed path;i.e., a path in which all nodes have exactly 2 neighbors. A cycle is a directed loop. A Directed Acyclic Graph (DAG) is a directed graph that has no cycles.

A fully connected directed graph is a directed graph in which every node has all other nodes as neighbors. Figs 4 and 5 show 2 different ways of drawing the same directed graph, a fully connected graph with 4 nodes. Note that a convenient way to label the nodes of a fully connected directed graph with $N$ nodes is to point arrows from $\underline{x}_{k}$ to $\underline{x}_{j}$ where $j=0,1,2, \ldots, N-1$ and $k=j-1, j-2, \ldots, 0$.

Figure 4: Fully connected directed graph with 4 nodes, drawn as a line.

Figure 5: Fully connected directed graph with 4 nodes, drawn as a square.
A connected graph is a graph for which there is no way of separating the nodes into two sets so that there is no arrow from one set to the other. A tree is a
directed graph in which all nodes have a single parent except for a single node called the "root" node which has no parents. A polytree is a DAG with no loops.

A Bayesian network (bnet) consists of a DAG and a Transition Probability Matrix (TPM) associated with each node of the graph. A TPM is often called a Conditional Probability Table (CPT). The structure of a bnet is its DAG alone, sans the TPMs. The skeleton of a bnet is the undirected graph beneath the bnet's DAG.

In this book, random variables are indicated by underlined letters and their values by non-underlined letters. Each node of a bnet is labelled by a random variable. Thus, $\underline{x}=x$ means that node $x$ is in state $x$.

## Some sets of nodes associated with each node $\underline{a}$ of a bnet

- $\operatorname{ch}(\underline{a})=$ children of $\underline{a}$.
- $p a(\underline{a})=$ parents of $\underline{a}$.
- $n b(\underline{a})=p a(\underline{a}) \cup c h(\underline{a})=$ neighbors of $\underline{a}$.
- $\operatorname{de}(\underline{a})=\cup_{n=1}^{\infty} \operatorname{ch}^{n}(\underline{a})=\operatorname{ch}(\underline{a}) \cup \operatorname{ch} \circ \operatorname{ch}(\underline{a}) \cup \ldots$, descendants of $\underline{a}$.
- $a n(\underline{a})=\cup_{n=1}^{\infty} p a^{n}(\underline{a})=p a(\underline{a}) \cup p a \circ p a(\underline{a}) \cup \ldots$, ancestors of $\underline{a}$.

In this book, we will use $\underline{a}$. to indicate a multi-node (node set, node array) $\underline{a} .=\left(\underline{a}_{j}\right)_{j=0,1, \ldots, n a-1}$. We will often treat multinodes as if they were sets, and combine them with the usual set operators. For instance, for two multinodes $\underline{a}$. and $\underline{b}$., we define $\underline{a} . \cup \underline{b}$., $\underline{a} . \cap \underline{b} ., \underline{a} .-\underline{b}$. and $\underline{a} . \subset \underline{b}$. in the obvious way. We will indicate a singleton set (single node multi-node) $\underline{a} .=\{\underline{a}\}$ simply by $\underline{a} .=\underline{a}$. For instance, $\underline{a} \cdot-\underline{b}=\underline{a} .-\{\underline{b}\}$.

The TPM of a node $\underline{x}$ of a bnet is a matrix of probabilities $P(\underline{x}=x \mid p a(\underline{x})=a$.$) .$ A bnet with nodes $\underline{x}$. represents a probability distribution

$$
\begin{equation*}
P(x .)=\prod_{j} P\left(\underline{x}_{j}=x_{j} \mid\left(\underline{x}_{k}=x_{k}\right)_{k: \underline{x}_{k} \in p a\left(\underline{x}_{j}\right)}\right) . \tag{106}
\end{equation*}
$$

Note that for a fully connected bnet with $N$ nodes, Eq.(106) becomes

$$
\begin{equation*}
P(x .)=\prod_{j=0}^{N-1} P\left(x_{j} \mid\left(x_{k}\right)_{k=j-1, j-2, \ldots, 0}\right) . \tag{107}
\end{equation*}
$$

For example, if $N=4$, Eq. 107) becomes

$$
\begin{equation*}
P\left(x_{0}, x_{1}, x_{2}, x_{3}\right)=P\left(x_{3} \mid x_{2}, x_{1}, x_{0}\right) P\left(x_{2} \mid x_{1}, x_{0}\right) P\left(x_{1} \mid x_{0}\right) P\left(x_{0}\right) . \tag{108}
\end{equation*}
$$

We see that Eq.(107) is just the chain rule for conditional probabilities.
Given an arbitrarily large dataset of samples for the random variables $\left(\underline{x}_{i}\right)_{i=0,1, \ldots, N-1}$, there may be several bnets (differing perhaps in the direction of some arrows) that fit the data well. However, according to Pearl's causality theory, only one of these
bnets is used by Nature. I like to refer to that single one as the causally correct (CC) Bayesian network ${ }^{\top}$ In this book, whenever we speak of causal issues, we will assume, often without mentioning it, that the CC bnet is being used $5^{5}$

[^2]
## Chapter 1

## ARACNE-structure learning

This chapter is based on Ref.[16].
The ARACNE algo is an algo for learning the structure of a bnet from data. The algo considers data samples for $n$ random variables $\left(x_{i}\right)_{i=0,1, \ldots, n-1}$, and estimates the mutual information $M I_{i, j}=H\left(\underline{x}_{i}: \underline{x}_{j}\right)$ between every pair of nodes. The set $U G$ is initialized to contain all the edges of a fully connected undirected graph. Next the algo removes from $U G$ every edge with $M I_{i, j}<\epsilon$ for some threshold $0<\epsilon \ll 1$. Then the algo examines every triplet of edges in $U G$, and marks for removal the edge of the triplet with the smallest MI. Finally, the algo removes from $U G$ all edges marked for removal. Each triplet is analyzed irrespective of whether its edges have been marked for removal when considering a prior triplet. Thus the network constructed by the algorithm is independent of the order in which the triplets are examined. Some of the unoriented edges in $U G$ can be given an orientation using the same techniques used to orient edges in constraint based structure learning (see Chapter 49).

Ref. [16] incorrectly claims that removing the smaller of 3 MI's is "an application" of the Data Processing Inequality (DPI) of Shannon Information Theory. See Chapter 30 for more info about DPI. Note that DPI is only valid for a Markov chain, and not all triplets of random variables are in a Markov chain. Removing the smaller of 3 numbers does not require DPI.

Fig 1.1 gives an example of the application of the ARACNE algo.
See Chapter 8 on Chow-Liu trees (CLT). A CLT is just a maximum spanning tree where the weights are mutual informations $M I_{i, j}$ estimated from data.

Sometimes, the outcome of the ARACNE algo is a CLT. For example, Fig. 1.1 (a) was considered in Chapter 8 on CLTs, and the CLT algo also gave Fig 1.1 ( $c$ ) as the final structure.

According to Ref.[16], the ARACNE algo sometimes yields a polytree (i.e., a connected graph with no loops). It may even yield a structure with loops. Hence, it does not always yield a CLT.

By breaking all cliques (i.e., fully connected subgraphs) with 3 edges and 3 nodes, ARACNE breaks all cliques with 3 or more nodes. However, cliques are not uncommon in Nature, especially 3 node cliques. Cliques become less likely in Nature

Figure 1.1: An example where the ARACNE algo gives a Chow-Liu tree. (a) Fully connected undirected graph with weights $M I_{i, j}$ along the edges. (b) All 4 possible triplets of edges with nonzero weights. Edges marked for removal have their weights printed in red.(c) Final structure.
the bigger the number of nodes they have after 3 . Therefore, a nice generalization of ARACNE would be to list all 4 node cliques, and break each of them by eliminating their edge with the smallest MI. This will have the effect of breaking all cliques with 4 or more nodes but keeping 3 node cliques. One could also break some, not all, of the 3 node cliques, by consecutively removing the clique-breaking-edge with the smallest MI of all edges of all 3 node cliques. Let $\beta$ stand for banned clique number of nodes. Then the current ARACNE has $\beta=3$. We are suggesting that a $\beta$ of 4 might be more likely to occur in Nature.

## Chapter 2

## Backdoor Adjustment

The backdoor (BD) adjustment theorem is proven in Chapter 13 from the rules of docalculus. The goal of this chapter is to give examples of the use of that theorem. We will restate the theorem in this chapter, sans proof. There is no need to understand the theorem's proof in order to use it. However, you will need to skim Chapter 13 in order to familiarize yourself with the notation used to state the theorem. This chapter also assumes that you are comfortable with the rules for checking for d-separation. Those rules are covered in Chapter 14.

Suppose that we have access to data that allows us to estimate a probability distribution $P(x ., y ., z$.$) . Hence, the variables \underline{x} ., \underline{y} ., \underline{z}$. are ALL the observed (i.e, not hidden). Then we say that the backdoor $\underline{z}$. satisfies the backdoor adjustment criterion relative to ( $\underline{x} ., \underline{y}$.) if

1. All backdoor paths from $\underline{x}$. to $\underline{y}$. are blocked by $\underline{z}$.
2. $\underline{z} . \cap d e(\underline{x})=.\emptyset$.

## Claim 2 Backdoor Adjustment Theorem

If $\underline{z}$. satisfies the backdoor criterion relative to (조., $\underline{y}$.), then

$$
\begin{align*}
& P(y . \mid \rho \underline{x} .=x .)= \sum_{z \cdot} P(y . \mid x ., z .) P(z .)  \tag{2.1}\\
&= \underline{z} \cdot=z .  \tag{2.2}\\
& \sum_{z .} \\
& \underline{x} \cdot=x . \longrightarrow \underline{y} .
\end{align*}
$$

proof: See Chapter 13
QED

### 2.1 Examples

1. 

BD criterion satisfied if $\underline{x} .=\underline{x}, \underline{y} .=\underline{y}, \underline{z} .=\emptyset$. No adjustment necessary.

$$
\begin{equation*}
P(y \mid \rho \underline{x}=x)=P(y \mid x) \tag{2.4}
\end{equation*}
$$

2. 

BD criterion satisfied if $\underline{x} .=\underline{x}, \underline{y} .=\underline{y}, \underline{z} .=\underline{z}$.
Note that here the backdoor formula adjusts the parents of $x$..
3.

BD criterion satisfied if $\underline{x} .=\underline{x}, \underline{y} .=\underline{y}, \underline{z} .=\underline{z}$.
4.

BD criterion is impossible to satisfy if $\underline{x} .=\underline{x}, \underline{y} .=\underline{y}$. However, the front-door criterion can be satisfied. See Chapter 17.
5.

BD criterion satisfied if $\underline{x} .=\underline{x}, \underline{y} .=\underline{y}, \underline{z} .=\underline{z}$. Note that here the backdoor formula cannot adjust the single parent $\underline{w}$ of $\underline{x}$ because it is hidden, but we are able to block the backdoor path by conditioning on $\underline{z}$ instead.
6.

Conditioning on $\underline{z}$ blocks backdoor path $\underline{x}-\underline{z}-\underline{y}$, but opens path $\underline{x}-\underline{e}-\underline{z}-\underline{a}-\underline{y}$ because $\underline{z}$ is a collider for that path. That path is blocked if we also condition on $\underline{a}$, which is possible because $\underline{a}$ is observed. In conclusion, the BD criterion is satisfied if $\underline{x} .=\underline{x}, \underline{y} .=\underline{y}$ and $\underline{z} .=(\underline{z}, \underline{a})$.
Conditioning on the parents of $\underline{x}$. is often enough to block all backdoor paths. However, sometimes some of the parents are unobserved and one must condition on other nodes that are not parents of $x$. in order to satisfy the BD criterion.
7.

No need to control anything because only possible backdoor path is blocked by collider $\underline{w}$. Hence,

$$
\begin{equation*}
P(y \mid \rho \underline{x}=x)=P(y \mid x) . \tag{2.11}
\end{equation*}
$$

However, if for some reason we want to control $\underline{t}$, we can do so. We can't control $\underline{w}$ though, because $\underline{w} \in d e(\underline{x})$. Thus, the BD criterion is satisfied if $\underline{x} .=\underline{x}, \underline{y} .=\underline{y}$ and $\underline{z} .=\underline{t}$. Therefore,

$$
\begin{equation*}
P(y \mid \rho \underline{x}=x)=\sum_{t} P(y \mid x, t) P(t) . \tag{2.12}
\end{equation*}
$$

8. Discuss reasons why multiple possible sets $\underline{z}$. that satisfy the BD criterion can be advantageous.

- Can evaluate $P(y . \mid \rho \underline{x} .=x$. $)$ multiple ways and compare the results. This is a test that the causal bnet is correct.
- It might be easier or less expensive to get data for some $\underline{z}$. more than for others.

9. (Taken from online course notes Ref.[11])

Consider the bnet

If $\underline{x}$. $=\underline{x}_{1}$ and $\underline{y}$. $=\underline{x}_{5}$, find all possible adjustment multinodes $\underline{z}$. that satisfy the BD criterion. Ans:

- $\emptyset$
- $\underline{x}_{4}$
- $\underline{x}_{2}, \underline{x}_{3}$
- $\underline{x}_{2}, \underline{x}_{3}, \underline{x}_{4}$
- $\underline{x}_{2}$
- $\underline{x}_{2}, \underline{x}_{4}$
- $\underline{x}_{3}, \underline{x}_{4}$

Add $\underline{x}_{7}$ to each of the previous 7 possible $\underline{z}$.. This gives a total of 14 possible adjustment multinodes $\underline{z}$..

## Chapter 3

## Back Propagation (Automatic Differentiation)

### 3.1 General Theory

### 3.1.1 Jacobians

Suppose $f: \mathbb{R}^{n x} \rightarrow \mathbb{R}^{n f}$ and

$$
\begin{equation*}
y=f(x) \tag{3.1}
\end{equation*}
$$

Then the Jacobian $\frac{\partial y}{\partial x}$ is defined as the matrix with entries ${ }^{1}$

$$
\begin{equation*}
\left[\frac{\partial y}{\partial x}\right]_{i, j}=\frac{\partial y_{i}}{\partial x_{j}} . \tag{3.2}
\end{equation*}
$$

Jacobian of function composition. Supoose $f: \mathbb{R}^{n x} \rightarrow \mathbb{R}^{n f}, g: \mathbb{R}^{n f} \rightarrow \mathbb{R}^{n g}$. If

$$
\begin{equation*}
y=g \circ f(x) \tag{3.3}
\end{equation*}
$$

then

$$
\begin{equation*}
\frac{\partial y}{\partial x}=\frac{\partial g}{\partial f} \frac{\partial f}{\partial x} . \tag{3.4}
\end{equation*}
$$

Right hand side of last equation is a product of two matrices so order of matrices is important.

$$
\begin{aligned}
& \underline{f}^{4} \longleftarrow \underline{f}^{3} \longleftarrow \underline{f}^{2} \longleftarrow \underline{f}^{1} \longleftarrow \underline{f}^{0} \\
& \text { (a) Composition } \\
& \text { (b) Forward-p } \\
& \text { (c) Back-p }
\end{aligned}
$$

Figure 3.1: bnets for function composition, forward propagation and back propagation for $n f=5$ nodes.

### 3.1.2 bnets for function composition, forward propagation and back propagation

Let

$$
\begin{equation*}
y=f^{4} \circ f^{3} \circ f^{2} \circ f^{1}(x) \tag{3.5}
\end{equation*}
$$

This function composition chain can be represented by the bnet Fig 3.1 ( a ) with TPMs

$$
\begin{equation*}
P\left(f^{\mu} \mid f^{\mu-1}\right)=\mathbb{1}\left(f^{\mu}=f^{\mu}\left(f^{\mu-1}\right)\right) \tag{3.6}
\end{equation*}
$$

for $\mu=1,2,3,4$.

[^3]Note that

$$
\begin{align*}
\frac{\partial y}{\partial x} & =\frac{\partial y}{\partial f^{3}} \frac{\partial f^{3}}{\partial f^{2}}\left[\frac{\partial f^{2}}{\partial f^{1}} \frac{\partial f^{1}}{\partial x}\right]  \tag{3.7}\\
& =\frac{\partial y}{\partial f^{3}}\left[\frac{\partial f^{3}}{\partial f^{2}} \frac{\partial f^{2}}{\partial x}\right]  \tag{3.8}\\
& =\left[\frac{\partial y}{\partial f^{3}} \frac{\partial f^{3}}{\partial x}\right]  \tag{3.9}\\
& =\frac{\partial y}{\partial x} \tag{3.10}
\end{align*}
$$

This forward propagation can be represented by the bnet Fig $3.1(b)$ with node TPMs

$$
\begin{equation*}
P\left(\left.\frac{\partial f^{\mu+1}}{\partial x} \right\rvert\, \frac{\partial f^{\mu}}{\partial x}\right)=\mathbb{1}\left(\frac{\partial f^{\mu+1}}{\partial x}=\frac{\partial f^{\mu+1}}{\partial f^{\mu}} \frac{\partial f^{\mu}}{\partial x}\right) \tag{3.11}
\end{equation*}
$$

for $\mu=1,2,3$.
Note that

$$
\begin{align*}
\frac{\partial y}{\partial x} & =\left[\frac{\partial y}{\partial f^{3}} \frac{\partial f^{3}}{\partial f^{2}}\right] \frac{\partial f^{2}}{\partial f^{1}} \frac{\partial f^{1}}{\partial x}  \tag{3.12}\\
& =\left[\frac{\partial y}{\partial f^{2}} \frac{\partial f^{2}}{\partial f^{1}}\right] \frac{\partial f^{1}}{\partial x}  \tag{3.13}\\
& =\left[\frac{\partial y}{\partial f^{1}} \frac{\partial f^{1}}{\partial x}\right]  \tag{3.14}\\
& =\frac{\partial y}{\partial x} \tag{3.15}
\end{align*}
$$

This back propagation can be represented by the bnet Fig 3.1 (c) with node TPMs

$$
\begin{equation*}
P\left(\frac{\partial y}{\partial f^{\mu}} \left\lvert\, \frac{\partial y}{\partial f^{\mu+1}}\right.\right)=\mathbb{1}\left(\frac{\partial y}{\partial f^{\mu}}=\frac{\partial y}{\partial f^{\mu+1}} \frac{\partial f^{\mu+1}}{\partial f^{\mu}}\right) \tag{3.16}
\end{equation*}
$$

for $\mu=2,1,0$.
$\frac{\partial f^{\mu+1}}{\partial f^{\mu}}$ is a Jacobian matrix so the order of multiplication matters. In forward prop, it pre-multiplies, and in back prop it post-multiplies.

### 3.2 Application to Neural Networks

### 3.2.1 Absorbing $b_{i}^{\lambda}$ into $w_{i \mid j}$.

Below are, printed in blue, the TPMs for the nodes of a NN bnet, as given in Chapter 35.

Figure 3.2: Nodes $\underline{h}_{0}^{0}, \underline{h}_{0}^{1}, \underline{Y}_{0}$ are all set to 1 . They allow us to absorb $b_{i}^{\lambda}$ into the first column of $w_{i \mid j}^{\lambda}$.

For all hidden layers $\lambda=0,1, \ldots, \Lambda-2$,

$$
\begin{equation*}
P\left(h_{i}^{\lambda} \mid h_{\cdot}^{\lambda-1}\right)=\delta\left(h_{i}^{\lambda}, \mathcal{A}_{i}^{\lambda}\left(\sum_{j} w_{i \mid j}^{\lambda} h_{j}^{\lambda-1}+b_{i}^{\lambda}\right)\right) \tag{3.17}
\end{equation*}
$$

for $i=0,1, \ldots, n h(\lambda)-1$. For the output visible layer $\lambda=\Lambda-1$ :

$$
\begin{equation*}
P\left(Y_{i} \mid h_{\cdot}^{\Lambda-2}\right)=\delta\left(Y_{i}, \mathcal{A}_{i}^{\Lambda-1}\left(\sum_{j} w_{i \mid j}^{\Lambda-1} h_{j}^{\Lambda-2}+b_{i}^{\Lambda-1}\right)\right) \tag{3.18}
\end{equation*}
$$

for $i=0,1, \ldots, n y-1$.
For each $\lambda$, replace the matrix $w_{\dot{\gamma}}^{\lambda}$ by the augmented matrix $\left[b^{\lambda} ., w_{\|}^{\lambda}\right]$ ] so that the new $w_{.}^{\lambda}$. satisfies

$$
\begin{equation*}
w_{i \mid 0}^{\lambda}=b_{i}^{\lambda} \tag{3.19}
\end{equation*}
$$

Let the nodes $\underline{h}_{0}^{\lambda}$ for all $\lambda$ and $\underline{Y}_{0}$ be root nodes (so no arrows pointing into them). For each $\lambda$, draw arrows from $\underline{h}_{0}^{\lambda}$ to all other nodes in that same layer. Draw arrows from $\underline{Y}_{0}$ to all other nodes in that same layer.

After performing the above steps, the TPMs, printed in blue, for the nodes of the NN bnet are as follows:

For all hidden layers $\lambda=0,1, \ldots, \Lambda-2$,

$$
\begin{equation*}
P\left(h_{0}^{\lambda}\right)=\delta\left(h_{0}^{\lambda}, 1\right), \tag{3.20}
\end{equation*}
$$

and

$$
\begin{equation*}
P\left(h_{i}^{\lambda} \mid h_{\cdot}^{\lambda-1}, h_{0}^{\lambda}=1\right)=\delta\left(h_{i}^{\lambda}, \mathcal{A}_{i}^{\lambda}\left(\sum_{j} w_{i \mid j}^{\lambda} h_{j}^{\lambda-1}\right)\right) \tag{3.21}
\end{equation*}
$$

for $i=1, \ldots, n h(\lambda)-1$. For the output visible layer $\lambda=\Lambda-1$ :

$$
\begin{equation*}
P\left(Y_{0}\right)=\delta\left(Y_{0}, 1\right) \tag{3.22}
\end{equation*}
$$

and

$$
\begin{equation*}
P\left(Y_{i} \mid h_{\cdot}^{\Lambda-2}, Y_{0}=1\right)=\delta\left(Y_{i}, \mathcal{A}_{i}^{\Lambda-1}\left(\sum_{j} w_{i \mid j}^{\Lambda-1} h_{j}^{\Lambda-2}\right)\right) \tag{3.23}
\end{equation*}
$$

for $i=1,2, \ldots, n y-1$.

### 3.2.2 bnets for function composition, forward propagation and back propagation for NN

(a)
$\frac{\partial \mathcal{A}^{3}}{\partial x} \longleftarrow \frac{\partial \mathcal{B}^{3}}{\partial x} \longleftarrow \frac{\partial \mathcal{A}^{2}}{\partial x} \longleftarrow \frac{\partial \mathcal{B}^{2}}{\partial x} \longleftarrow \frac{\partial \mathcal{A}^{1}}{\partial x} \longleftarrow \frac{\partial \mathcal{B}^{1}}{\partial x} \longleftarrow \frac{\partial \mathcal{A}^{0}}{\partial x} \longleftarrow \frac{\partial \mathcal{B}^{0}}{\partial x} \longleftarrow \underline{1}$
(b)

$$
\underline{1} \longrightarrow \frac{\partial Y}{\underline{\partial \mathcal{B}^{3}}} \longrightarrow \frac{\partial Y}{\underline{\partial \mathcal{A}^{2}}} \longrightarrow \frac{\partial Y}{\underline{\partial \mathcal{B}^{2}}} \longrightarrow \frac{\partial Y}{\underline{\partial \mathcal{A}^{1}}} \longrightarrow \frac{\partial Y}{\underline{\partial \mathcal{B}^{1}}} \longrightarrow \frac{\partial Y}{\partial \mathcal{A}^{0}} \longrightarrow \frac{\partial Y}{\underline{\partial \mathcal{B}^{0}}} \longrightarrow \frac{\partial Y}{\partial x}
$$

(c)

Figure 3.3: bnets for (a) function composition, (b) forward propagation and (c) back propagation for a neural net with 4 layers (3 hidden and output visible).

From here on, we will rename $y$ above by $Y=\hat{y}$ and consider samples $y[i]$ for $i=$ $0,1, \ldots$, nsam -1 . The Error (aka loss or cost function) is

$$
\begin{equation*}
\mathcal{E}=\frac{1}{n s a m} \sum_{\sigma=0}^{n s a m-1} \sum_{i=0}^{n y-1}\left|Y_{i}-y_{i}[\sigma]\right|^{2} \tag{3.24}
\end{equation*}
$$

To perform simple gradient descent, one uses:

$$
\begin{equation*}
\left(w_{i \mid j}^{\lambda}\right)^{\prime}=w_{i \mid j}^{\lambda}-\eta \frac{\partial \mathcal{E}}{\partial w_{i \mid j}^{\lambda}} \tag{3.25}
\end{equation*}
$$

One has

$$
\begin{equation*}
\frac{\partial \mathcal{E}}{\partial w_{i \mid j}^{\lambda}}=\frac{1}{n s a m} \sum_{\sigma=0}^{n s a m-1} \sum_{i=0}^{n y-1} 2\left(Y_{i}-y_{i}[\sigma]\right) \frac{\partial Y}{\partial w_{i \mid j}^{\lambda}} \tag{3.26}
\end{equation*}
$$

Define $\mathcal{B}_{i}^{\lambda}$ thus

$$
\begin{equation*}
\mathcal{B}_{i}^{\lambda}\left(h^{\lambda-1}\right)=\sum_{j} w_{i \mid j}^{\lambda} h_{j}^{\lambda-1} \tag{3.27}
\end{equation*}
$$

Then

$$
\begin{align*}
\frac{\partial Y}{\partial w_{i \mid j}^{\lambda}} & =\frac{\partial Y}{\partial \mathcal{B}_{i}^{\lambda}} \frac{\partial \mathcal{B}_{i}^{\lambda}}{\partial w_{i \mid j}^{\lambda}}  \tag{3.28}\\
& =\frac{\partial Y}{\partial \mathcal{B}_{i}^{\lambda}} h_{j}^{\lambda-1}  \tag{3.29}\\
\frac{\partial \mathcal{E}}{\partial w_{i \mid j}^{\lambda}} & =\frac{\partial \mathcal{E}}{\partial \mathcal{B}_{j}^{\lambda}} \frac{\partial \mathcal{B}_{j}^{\lambda}}{\partial w_{i \mid j}^{\lambda}}  \tag{3.30}\\
& =\frac{\partial \mathcal{E}}{\partial \mathcal{B}_{j}^{\lambda}} h_{j}^{\lambda-1} . \tag{3.31}
\end{align*}
$$

This suggest that we can calculate the derivatives of the error $\mathcal{E}$ with respect to the weights $w_{i \mid j}^{\lambda}$ in two stages, using an intermediate quantity $\delta_{j}^{\lambda}$ :

$$
\left\{\begin{array}{l}
\delta_{j}^{\lambda}=\frac{\partial \mathcal{E}}{\partial \mathcal{B}_{j}^{\lambda}}  \tag{3.32}\\
\frac{\partial \mathcal{E}}{\partial w_{i \mid j}^{\lambda}}=\delta_{j}^{\lambda} h_{j}^{\lambda-1}
\end{array}\right.
$$

To apply what we learned in the earlier General Theory section of this chapter, consider a NN with 4 layers ( 3 hidden, and the output visible one). Define the functions $f_{i}$ as follows:

$$
\begin{equation*}
f_{i}^{0}=x_{i} \tag{3.33}
\end{equation*}
$$

Layer 0: $\quad f_{i}^{1}=\mathcal{B}_{i}^{0}\left(x_{i}\right), \quad f_{i}^{2}=\mathcal{A}_{i}^{0}\left(\mathcal{B}_{i}^{0}\right)$
Layer 1: $\quad f_{i}^{3}=\mathcal{B}_{i}^{1}\left(\mathcal{A}_{i}^{0}\right), \quad f_{i}^{4}=\mathcal{A}_{i}^{1}\left(\mathcal{B}_{i}^{1}\right)$
Layer 2: $\quad f_{i}^{5}=\mathcal{B}_{i}^{2}\left(\mathcal{A}_{i}^{1}\right), \quad f_{i}^{6}=\mathcal{A}_{i}^{2}\left(\mathcal{B}_{i}^{2}\right)$
Layer 3: $\quad f_{i}^{7}=\mathcal{B}_{i}^{3}\left(\mathcal{A}_{i}^{2}\right), \quad f_{i}^{8}=\mathcal{A}_{i}^{3}\left(\mathcal{B}_{i}^{3}\right)$

See Fig 3.3. The TPMs, printed in blue, for the nodes of the bnet $(c)$ for back propagation, are:

$$
\begin{equation*}
P\left(\frac{\partial Y}{\partial \mathcal{B}^{\lambda}} \left\lvert\, \frac{\partial Y}{\partial \mathcal{B}^{\lambda+1}}\right.\right)=\mathbb{1}\left(\frac{\partial Y}{\partial \mathcal{B}^{\lambda}}=\frac{\partial Y}{\partial \mathcal{B}^{\lambda+1}} \frac{\partial \mathcal{B}^{\lambda+1}}{\partial \mathcal{A}^{\lambda}} \frac{\partial \mathcal{A}^{\lambda}}{\partial \mathcal{B}^{\lambda}}\right) . \tag{3.38}
\end{equation*}
$$

One has

$$
\begin{equation*}
\frac{\partial \mathcal{A}_{i}^{\lambda}}{\partial \mathcal{B}_{j}^{\lambda}}=D \mathcal{A}_{i}{ }^{\lambda}\left(\mathcal{B}_{i}^{\lambda}\right) \delta(i, j) \tag{3.39}
\end{equation*}
$$

where $D \mathcal{A}_{i}^{\lambda}(z)$ is the derivative of $\mathcal{A}_{i}^{\lambda}(z)$.
From Eq. 3.27)

$$
\begin{equation*}
\mathcal{B}_{i}^{\lambda+1}\left(\mathcal{A}^{\lambda}\right)=\sum_{j} w_{i \mid j}^{\lambda+1} \mathcal{A}_{j}^{\lambda} \tag{3.40}
\end{equation*}
$$

so

$$
\begin{equation*}
\frac{\partial \mathcal{B}_{i}^{\lambda+1}}{\partial \mathcal{A}_{j}^{\lambda}}=w_{i \mid j}^{\lambda+1} \tag{3.41}
\end{equation*}
$$

Therefore, Eq.(3.38) implies

$$
\begin{gather*}
P\left(\frac{\partial Y}{\partial \mathcal{B}_{j}^{\lambda}} \left\lvert\, \frac{\partial Y}{\partial \mathcal{B}_{j}^{\lambda+1}}\right.\right)=\mathbb{1}\left(\frac{\partial Y}{\partial \mathcal{B}_{j}^{\lambda}}=\sum_{i} \frac{\partial Y}{\partial \mathcal{B}_{i}^{\lambda+1}} D \mathcal{A}_{j}^{\lambda}\left(\mathcal{B}_{j}^{\lambda}\right) w_{i \mid j}^{\lambda+1}\right),  \tag{3.42}\\
P\left(\frac{\partial \mathcal{E}}{\partial \mathcal{B}_{j}^{\lambda}} \left\lvert\, \frac{\partial \mathcal{E}}{\partial \mathcal{B}_{j}^{\lambda+1}}\right.\right)=\mathbb{1}\left(\frac{\partial \mathcal{E}}{\partial \mathcal{B}_{j}^{\lambda}}=\sum_{i} \frac{\partial \mathcal{E}}{\partial \mathcal{B}_{i}^{\lambda+1}} D \mathcal{A}_{j}^{\lambda}\left(\mathcal{B}_{j}^{\lambda}\right) w_{i \mid j}^{\lambda+1}\right),  \tag{3.43}\\
\left.P\left(\delta_{j}^{\lambda} \mid \delta_{j}^{\lambda+1}\right)=\mathbb{1}\left(\delta_{j}^{\lambda}=\sum_{i} \delta_{i}^{\lambda+1} D \mathcal{A}_{j}^{\lambda}\left(\mathcal{B}_{j}^{\lambda}\right)\right) w_{i \mid j}^{\lambda+1}\right) . \tag{3.44}
\end{gather*}
$$

First delta of iteration, belonging to output layer $\lambda=\Lambda-1$ :

$$
\begin{align*}
\delta_{j}^{\Lambda-1} & =\frac{\partial \mathcal{E}}{\partial \mathcal{B}_{j}^{\Lambda-1}}  \tag{3.45}\\
& =\frac{1}{n s a m} \sum_{\sigma=0}^{n s a m-1} \sum_{i=0}^{n y-1} 2\left(Y_{i}-y_{i}[\sigma]\right) D \mathcal{A}_{i}^{\Lambda-1}\left(\mathcal{B}_{i}^{\Lambda-1}\right) \delta(i, j)  \tag{3.46}\\
& =\frac{1}{n s a m} \sum_{\sigma=0}^{n s a m-1} 2\left(Y_{j}-y_{j}[\sigma]\right) D \mathcal{A}_{j}^{\Lambda-1}\left(\mathcal{B}_{j}^{\Lambda-1}\right) \tag{3.47}
\end{align*}
$$

Cute expression for derivative of sigmoid function:

$$
\begin{equation*}
D \operatorname{sig}(x)=\operatorname{sig}(x)(1-\operatorname{sig}(x)) \tag{3.48}
\end{equation*}
$$

### 3.3 General bnets instead of Markov chains induced by layered structure of NNs

$$
\begin{equation*}
\left.P\left(\delta_{\underline{x}} \mid\left(\delta_{\underline{a}}\right)_{\underline{a} \in c h(\underline{x})}\right)=\mathbb{1}\left(\delta_{\underline{x}}=\sum_{\underline{a} \in \operatorname{ch}(\underline{x})} \delta_{\underline{a}} D \mathcal{A}_{\underline{x}}\left(\mathcal{B}_{\underline{x}}\right)\right) w_{\underline{a} \mid \underline{x}}\right) \tag{3.49}
\end{equation*}
$$

Reverse arrows of original bnet and define the TPM of nodes of "time reversed" bnet by

$$
\begin{equation*}
\left.P\left(\delta_{\underline{x}} \mid\left(\delta_{\underline{a}}\right)_{\underline{a} \in p a(\underline{x})}\right)=\mathbb{1}\left(\delta_{\underline{x}}=\sum_{\underline{a} \in p a(\underline{x})} \delta_{\underline{a}} D \mathcal{A}_{\underline{x}}\left(\mathcal{B}_{\underline{x}}\right)\right) w_{\underline{x} \mid \underline{a}}^{T}\right) \tag{3.50}
\end{equation*}
$$

## Chapter 4

## Basic Curve Fitting Using Gradient Descent

Figure 4.1: Basic curve fitting bnet.
Samples $(x[\sigma], y[\sigma]) \in S_{\underline{x}} \times S_{\underline{y}}$ are given. $\operatorname{nsam}(\vec{x})=\operatorname{nsam}(\vec{y})$.
Estimator function $\hat{y}(x ; \phi)$ for $x \in S_{\underline{x}}$ and $\phi \in \mathbb{R}$ is given.
Let

$$
\begin{equation*}
P_{\underline{x}, \underline{y}}(x, y)=\frac{1}{\operatorname{nsam}(\vec{x})} \sum_{\sigma} \mathbb{1}(x=x[\sigma], y=y[\sigma]) . \tag{4.1}
\end{equation*}
$$

Let

$$
\begin{equation*}
\mathcal{E}(\vec{x}, \vec{y}, \phi)=\frac{1}{n \operatorname{sam}(\vec{y})} \sum_{\sigma}|y[\sigma]-\hat{y}(x[\sigma] ; \phi)|^{2} \tag{4.2}
\end{equation*}
$$

$\mathcal{E}$ is called the mean square error.
Best fit is parameters $\phi^{*}$ such that

$$
\begin{equation*}
\phi^{*}=\underset{\phi}{\operatorname{argmin}} \mathcal{E}(\vec{x}, \vec{y}, \phi) . \tag{4.3}
\end{equation*}
$$

The node TPMs for the basic curve fitting bnet Fig 4.1 are printed below in blue.

$$
\begin{equation*}
P(\phi)=\text { given } . \tag{4.4}
\end{equation*}
$$

The first time it is used, $\phi$ is arbitrary. After the first time, it is determined by previous stage.

$$
\begin{gather*}
P(\vec{x})=\prod_{\sigma} P_{\underline{x}}(x[\sigma])  \tag{4.5}\\
P(\vec{y} \mid \vec{x})=\prod_{\sigma} P_{\underline{y} \mid \underline{x}}(y[\sigma] \mid x[\sigma])  \tag{4.6}\\
P(\hat{y}[\sigma] \mid \phi, \vec{x})=\delta(\hat{y}[\sigma], \hat{y}(x[\sigma] ; \phi))  \tag{4.7}\\
P(\mathcal{E} \mid \overrightarrow{\hat{y}}, \vec{y})=\delta\left(\mathcal{E}, \frac{1}{n \operatorname{sam}(\vec{x})} \sum_{\sigma}|y[\sigma]-\hat{y}[\sigma]|^{2}\right) .  \tag{4.8}\\
P\left(\phi^{\prime} \mid \phi, \mathcal{E}\right)=\delta\left(\phi^{\prime}, \phi-\eta \partial_{\phi} \mathcal{E}\right) \tag{4.9}
\end{gather*}
$$

$\eta>0$ is the descent rate. If $\Delta \phi=\phi^{\prime}-\phi=-\eta \frac{\partial \mathcal{E}}{\partial \phi}$, then $\Delta \mathcal{E}=\frac{-1}{\eta}(\Delta \phi)^{2}<0$ so this will minimize the error $\mathcal{E}$. This is called "gradient descent".

## Chapter 5

# Bell and Clauser-Horne Inequalities in Quantum Mechanics 

Figure 5.1: bnet used to discuss Bell and Clauser-Horne inequalities in Quantum Mechanics.

I wrote an article about this in 2008 for my blog "Quantum Bayesian Networks". See Ref. [39].

## Chapter 6

## Berkson's Paradox

For more information about Berkson's Paradox (BP), see Ref. 43 ]

Figure 6.1: Bnet used to discuss Berkson's Paradox (BP). $\underline{a}$ and $\underline{b}$ are common causes of collider $\underline{x}$.

Consider the bnet of Fig.6.1. For that bnet, we have

$$
\begin{equation*}
P(a, b, x)=P(a) P(b) P(x \mid a, b) . \tag{6.1}
\end{equation*}
$$

Summing Eq.(6.1) over $x$, we get

$$
\begin{equation*}
P(a, b)=P(a) P(b) \tag{6.2}
\end{equation*}
$$

so $\underline{a}$ and $\underline{b}$ are independent. It follows that $a$ can be ignored in calculating the probability of $b$; i.e.,

$$
\begin{equation*}
P(b \mid a)=P(b) \text {. } \tag{6.3}
\end{equation*}
$$

However, $a$ cannot be ignored in calculating the probability of $b$, if $x$ is being held fixed; i.e.,

$$
\begin{equation*}
P(b \mid a, x) \neq P(b \mid x) \text {. } \tag{6.4}
\end{equation*}
$$

Indeed,

$$
\begin{equation*}
P(b \mid a, x)=\frac{P(b) P(x \mid a, b)}{\sum_{b} P(b) P(x \mid a, b)} \tag{6.5}
\end{equation*}
$$

whereas

$$
\begin{equation*}
P(b \mid x)=\frac{\sum_{a} P(a) P(b) P(x \mid a, b)}{\sum_{a, b} P(a) P(b) P(x \mid a, b)} . \tag{6.6}
\end{equation*}
$$

The two boxed equations are what is referred to as BP.
BP is also called collider bias because $\underline{x}$ is a collider.
BP is also called explaining away in the special case that $\underline{a}, \underline{b}, \underline{x} \in\{$ true, false $\}=$ $\{0,1\}$. In that case, if $\underline{x}$ is fixed to true, and the cause $\underline{a}$ is known to be true, then the cause $\underline{b}$ is less likely to be true. For example, suppose a car engine fails $(\underline{x}=1)$ and the two most likely causes of the failure are alternator $(\underline{a})$ and battery ( $\underline{b}$ ). Once we know that the alternator has failed ( $\underline{a}=1$ ), it is less likely that the battery is failing $(\underline{b}=1)$ than when the status of $\underline{a}$ was not known; i.e., $P(b=1 \mid x=1, a=1)<P(b=1 \mid x=1)$.

Figure 6.2: Example of Berkson's paradox (BP).
Fig 6.2 presents an example of BP . The figure consists of a scatter plot with axes $\mathrm{x}=$ intelligence, $\mathrm{y}=$ attractiveness, for a population of possible dates for a single person. For the full population,

$$
\begin{equation*}
(a, b) \sim P(a, b)=P(a) P(b) \tag{6.7}
\end{equation*}
$$

whereas for the population in the white swath,

$$
\begin{equation*}
(a, b) \sim P(a, b \mid x)=P(b \mid a, x) P(a \mid x) \neq P(b \mid x) P(a \mid x) . \tag{6.8}
\end{equation*}
$$

As shown by Fig 6.2, BP is an example of selection bias. Selection bias happens when a non-representative subset of the total population is considered (i.e., selected).

## Chapter 7

## Binary Decision Diagrams

Figure 7.1: Binary decision tree and truth table for the function $f\left(x_{1}, x_{2}, x_{3}\right)=$ $\bar{x}_{1}\left(x_{2}+\bar{x}_{3}\right)+x_{1} x_{2}$

Figure 7.2: BDD for the function $f$ of Fig. 7.1.

This chapter is based on Wikipedia article Ref. [45].
Binary Decision Diagrams (BDDs) can be understood as a special case of Decision Trees (dtrees). We will assume that the reader has read Chapter 10 on dtrees before reading this chapter.

Both Figs. 7.1 and 7.2 were taken from the aforementioned Wikipedia article. They give a simple example of a function $f:\{0,1\}^{3} \rightarrow\{0,1\}$ represented in Fig. 7.1 as a binary decision tree and in Fig 7.2 as a binary decision diagram (BDD). It is possible to find, for each of those two figures, a bnet with the same graph structure. We show how to do this next.

We begin by noting that the function $f:\{0,1\}^{3} \rightarrow\{0,1\}$ is a special case of a probability distribution $P:\{0,1\}^{3} \rightarrow[0,1]$. In fact, if we restrict $P$ to be deterministic, then $P_{\text {det }}:\{0,1\}^{3} \rightarrow\{0,1\}$ has the same domain and range as $f$. Henceforth, we will refer to $f\left(x_{1}, x_{2}, x_{3}\right)$ as $P\left(x_{1}, x_{2}, x_{3}\right)$, keeping in mind that we are restricting our attention to deterministic probability distributions.

If we apply the chain rule for conditional probabilities to $P\left(x_{1}, x_{2}, x_{3}\right)$, we get

$$
\begin{equation*}
P\left(x_{1}, x_{2}, x_{3}\right)=P\left(x_{3} \mid x_{1}, x_{2}\right) P\left(x_{2} \mid x_{1}\right) P\left(x_{1}\right), \tag{7.1}
\end{equation*}
$$

which can be represented by the bnet:

Figure 7.3: Most general 3 node bnet.
But in Chapter 10, we learned how to represent the dtree of Fig 7.1 as the image bnet Fig.7.4. The node TPMs, printed in blue, for the image bnet Fig. 7.4 are as follows. Note that the TPMs for Fig. 7.4 can be constructed from the TPMs for the bnet Fig.7.3. If $x_{1}, x_{2}, x_{3}, x_{4} \in\{0,1$, null $\}$ and $a, b, c \in\{0,1\}$, then

$$
\begin{gather*}
P\left(\underline{x_{1}}=x_{1}\right)= \begin{cases}P_{\underline{x_{1}}}\left(x_{1}\right) & \text { if } x_{1} \in\{0,1\} \\
0 & \text { if } x_{1}=\text { null }\end{cases}  \tag{7.2}\\
P\left(\underline{x_{2} \mid a}=x_{2} \mid \underline{x_{1}}=x_{1}\right)= \begin{cases}P_{x_{2}} \mid x_{1}\left(x_{2} \mid a\right) & \text { if } x_{1}=a \\
\mathbb{1}\left(x_{2}=\text { null }\right) & \text { otherwise }\end{cases}  \tag{7.3}\\
P\left(\underline{x_{3} \mid a, b}=x_{3} \mid \underline{x_{2} \mid a}=x_{2}\right)= \begin{cases}P_{x_{3}} \mid \underline{x}_{1}, x_{2}\left(x_{3} \mid a, b\right) & \text { if } x_{2}=b \\
\mathbb{1}\left(x_{3}=\text { null }\right) & \text { otherwise }\end{cases} \tag{7.4}
\end{gather*}
$$

Figure 7.4: Image bnet for binary dtree of Fig 7.1.

$$
P\left(\underline{x_{4} \mid a, b, c}=x_{4} \mid \underline{x_{3} \mid a, b}=x_{3}\right)= \begin{cases}\delta\left(x_{4}, c\right) & \text { if } x_{3}=c  \tag{7.5}\\ \mathbb{1}\left(x_{4}=\text { null }\right) & \text { otherwise }\end{cases}
$$

Note that if $P_{\underline{x}_{3}} \underline{\underline{x}} 1, \underline{x}_{2}=P_{\underline{x}_{3} \mid \underline{x}_{2}}$ in Eq. (7.4), then the bnet Fig 7.3 reduces to a Markov chain $\underline{x}_{1} \rightarrow \underline{x}_{2} \rightarrow \underline{x}_{3}$.

The BDD shown in Fig 7.2 emphasizes the fact that

$$
\begin{equation*}
P\left(x_{1}, x_{2}, x_{3} \mid x_{1}=1\right)=P\left(x_{2} \mid x_{1}=1\right)=x_{2} . \tag{7.6}
\end{equation*}
$$

The BDD of Fig 7.2 has as image bnet Fig.7.5. Define

$$
\begin{equation*}
p a(\underline{0})=p a(\underline{1})=\left(x_{2}\left|1, x_{3}\right| 00, x_{3} \mid 01\right) . \tag{7.7}
\end{equation*}
$$

Let $p a(\underline{0})=a b c$ mean the same as $p a(\underline{0})=(a, b, c)$. The TPMs of the image bnet Fig 7.5 are the same as those for the image bnet Fig 7.4 except for the TPMs of the nodes $\underline{0}$ and 1 . For those two nodes, the TPMs, printed in blue, are as follows.

$$
\begin{align*}
& P(\underline{0}=x \mid p a(\underline{0}))= \begin{cases}\delta(x, 0) & \text { if } p a(\underline{0})=011 \\
\delta(x, \text { null }) & \text { otherwise }\end{cases}  \tag{7.8}\\
& P(\underline{1}=x \mid p a(\underline{1}))= \begin{cases}\delta(x, 1) & \text { if } p a(\underline{1})=101 \\
\delta(x, \text { null }) & \text { otherwise }\end{cases} \tag{7.9}
\end{align*}
$$

Figure 7.5: Image bnet for BDD of Fig. 7.2 .

## Chapter 8

## Chow-Liu Trees and Tree Augmented Naive Bayes (TAN)

This chapter is mostly based on chapter 8 of Pearl's 1988 book Ref.[25]. See also Ref. [48] and references therein.

This chapter uses various Shannon Information Theory entropies. Our notation for these entropies is described in Chapter Notational Conventions and Preliminaries on Notational Conventions.

### 8.1 Chow-Liu Trees

Chow-Liu trees refers to an algorithm for finding a bnet tree that fits an a priori given probability distribution as closely as possible.

Consider a bnet with $n$ nodes $\underline{x}^{n}=\left(\underline{x}_{0}, \underline{x}_{1}, \ldots, \underline{x}_{n-1}\right)$ such that $\underline{x}_{i} \in S_{\underline{x}_{i}}$ for all $i$. Let its total probability distribution be $P_{\underline{x}^{n}}$. For simplicity, we will abbreviate $P_{\underline{x}^{n}}$ by $P$. Hence

$$
\begin{equation*}
P\left(x^{n}\right)=P_{\underline{x}^{n}}\left(x^{n}\right) . \tag{8.1}
\end{equation*}
$$

Suppose we want to fit $P_{\underline{x}^{n}}$ by a tree bnet with nodes $\underline{t}^{n}=\left(\underline{t}_{0}, \underline{t}_{1}, \ldots, \underline{t}_{n-1}\right)$ such that $\underline{t}_{i} \in S_{\underline{t}_{i}}=S_{\underline{x}_{i}}$ for all $i$. For simplicity, we will abbreviate $P_{\underline{t}^{n}}$ by $P_{T}$. Hence

$$
\begin{equation*}
P_{T}\left(x^{n}\right)=P_{\underline{t}^{n}}\left(x^{n}\right) . \tag{8.2}
\end{equation*}
$$

Throughout this chapter, let $V=\{0,1, \ldots, n-1\}$, the set of vertices. Suppose $\mu$ is a function $\mu: V \rightarrow V$ such that $\mu(i)<i$. Let $T_{\mu}=\left\{\underline{t}_{\mu(i)} \rightarrow \underline{t}_{i}: i \in V-\{0\}\right\}$. Then $T_{\mu}$ is a tree that spans (i.e., it includes all nodes) $\underline{t}^{n}$. Its root node is $\underline{t}_{0}$, because $\underline{t}_{0}$ has no parents. All other nodes $\underline{t}_{i}$ have exactly one parent, namely $\underline{t}_{\mu(i)}$. Let $P_{T}$, the total probability distribution for the tree, be parameterized by the function $\mu$ as
follows:

$$
\begin{equation*}
P_{T}\left(x^{n}\right)=\prod_{i=0}^{n-1} P_{T}\left(x_{i} \mid x_{\mu(i)}\right), \tag{8.3}
\end{equation*}
$$

where, for the root node $0, P_{T}\left(x_{0} \mid x_{\mu(0)}\right)=P_{T}\left(x_{0}\right)$.
Claim $3 D_{K L}\left(P \| P_{T}\right)$ is minimized over all probability distributions $P_{T}$ that are expressible as Eq. (8.3) iff

$$
\begin{equation*}
P_{T}\left(x_{i} \mid x_{\mu(i)}\right)=P\left(x_{i} \mid x_{\mu(i)}\right) \tag{8.4}
\end{equation*}
$$

for all i, and

$$
\begin{equation*}
\sum_{i} H\left(\underline{x}_{i}: \underline{x}_{\mu(i)}\right) \tag{8.5}
\end{equation*}
$$

is maximized over all $\mu$.
proof:

$$
\begin{align*}
D_{K L}\left(P \| P_{T}\right) & =\sum_{x^{n}} P\left(x^{n}\right) \ln \frac{P\left(x^{n}\right)}{P_{T}\left(x^{n}\right)}  \tag{8.6}\\
& =-\sum_{x^{n}} \sum_{i} P\left(x^{n}\right) \ln P_{T}\left(x_{i} \mid x_{\mu(i)}\right)+\sum_{i} P\left(x^{n}\right) \ln P\left(x^{n}\right)  \tag{8.7}\\
& =-\sum_{i} \sum_{x_{i}, x_{\mu(i)}} P\left(x_{i}, x_{\mu(i)}\right) \ln P_{T}\left(x_{i} \mid x_{\mu(i)}\right)-H\left(\underline{x}^{n}\right)  \tag{8.8}\\
& =-\sum_{i} \sum_{x_{\mu(i)}} P\left(x_{\mu(i)}\right)\left[\sum_{x_{i}} P\left(x_{i} \mid x_{\mu(i)}\right) \ln P_{T}\left(x_{i} \mid x_{\mu(i)}\right)\right]-H\left(\underline{x}^{n}\right) . \tag{8.9}
\end{align*}
$$

Now note that

$$
\begin{equation*}
\sum_{x_{i}} P\left(x_{i} \mid x_{\mu(i)}\right) \ln \frac{P\left(x_{i} \mid x_{\mu(i)}\right)}{P_{T}\left(x_{i} \mid x_{\mu(i)}\right)} \geq 0 \tag{8.10}
\end{equation*}
$$

and this inequality becomes an equality iff

$$
\begin{equation*}
P\left(x_{i} \mid x_{\mu(i)}\right)=P_{T}\left(x_{i} \mid x_{\mu(i)}\right) . \tag{8.11}
\end{equation*}
$$

Therefore

$$
\begin{equation*}
D_{K L}\left(P \| P_{T}\right) \geq-\sum_{i} \underbrace{\sum_{x_{\mu(i)}} P\left(x_{\mu(i)}\right)\left[\sum_{x_{i}} P\left(x_{i} \mid x_{\mu(i)}\right) \ln P\left(x_{i} \mid x_{\mu(i)}\right)\right]}_{=H\left(\underline{x}_{i} \mid \underline{x}_{\mu(i)}\right)=H\left(\underline{x}_{i}: \underline{x}_{\mu(i)}\right)-H\left(\underline{x}_{i}\right)}-H\left(\underline{x}^{n}\right), \tag{8.12}
\end{equation*}
$$

and this inequality becomes an equality iff Eq. (8.11) is satisfied.
Note from the last equation that

$$
\begin{equation*}
\underset{\mu}{\operatorname{argmin}} D_{K L}\left(P \| P_{T}\right)=\underset{\mu}{\operatorname{argmax}} \sum_{i} H\left(\underline{x}_{i}: \underline{x}_{\mu(i)}\right) . \tag{8.13}
\end{equation*}
$$

## QED

## Claim 4

$$
\begin{equation*}
\underset{\mu}{\operatorname{argmin}} H\left(\underline{x}^{n}\right)=\underset{\mu}{\operatorname{argmax}} \sum_{i} H\left(\underline{x}_{i}: \underline{x}_{\mu(i)}\right) \tag{8.14}
\end{equation*}
$$

proof:

$$
\begin{align*}
H\left(\underline{x}^{n}\right) & =-\sum_{x^{n}} P\left(x^{n}\right) \sum_{i} \ln P\left(x_{i} \mid x_{\mu(i)}\right)  \tag{8.15}\\
& =-\sum_{i} \sum_{x_{i}, x_{\mu(i)}} P\left(x_{i}, x_{\mu(i)}\right) \ln P\left(x_{i} \mid x_{\mu(i)}\right)  \tag{8.16}\\
& =-\sum_{i} \sum_{x_{i}, x_{\mu(i)}} P\left(x_{i}, x_{\mu(i)}\right)\left[\ln \frac{P\left(x_{i} \mid x_{\mu(i)}\right)}{P\left(x_{i}\right)}+\ln P\left(x_{i}\right)\right]  \tag{8.17}\\
& =-\sum_{i}\left[H\left(\underline{x}_{i}: \underline{x}_{\mu(i)}\right)-H\left(\underline{x}_{i}\right)\right]  \tag{8.18}\\
& =\sum_{i} H\left(\underline{x}_{i}\right)-\sum_{i} H\left(\underline{x}_{i}: \underline{x}_{\mu(i)}\right) \tag{8.19}
\end{align*}
$$

## QED

The meaning of Claims 3 and 4 is as follows. If $D_{K L}\left(P \| P_{T}\right)$ is minimized over all $P_{T}$, then

1. $P_{T}$ inherits its TPM's from $P$, and
2. $P_{T}$ gets its structure, which is being parameterized by the function $\mu$, by maximizing the score given by

$$
\begin{equation*}
\text { score }=\sum_{i} H\left(\underline{x}_{i}: \underline{x}_{\mu(i)}\right) . \tag{8.20}
\end{equation*}
$$

(mutual information $H(\underline{a}: \underline{b})$ measures correlation between $\underline{a}$ and $\underline{b}$ ). Maximizing the score is the same as minimizing the entropy $H\left(\underline{x}^{n}\right)$ over all the structures $\mu$. (i.e., finding least complex structure).

So far, we have studied the properties of those probability distributions $P_{T}$ for a tree bnet that best approximates an a priori given probability distribution $P$, but we haven't yet described how to build a Chow-Liu tree based on empirical data. Next we give Chow-Liu's algorithm for doing so.

## 1. Find MST using Kruskal's algorithm ${ }^{\text {T }}$, (see Fig 8.1)

Calculate weights $w_{i, j}=H\left(\underline{x}_{i}: \underline{x}_{j}\right)$ for all $i, j \in V$ and store them in a dictionary $D$ that maps edges to weights.
Order $D$ by weight size.
Let $T$ be a list of the edges in the tree. Initialize $T$ to empty.
Repeat this until $T$ has $n-1$ elements:
Remove largest weight $w$ from $D$ and corresponding edge $e$.
Add $e$ to $T$ if $\{e\} \cup T$ has no loops. Otherwise discard $e$ and $w$.
2. Give directions to edges in $T$. (see Fig 8.2)

Let $D T$ be a list of directed edges. Initialize $D T$ to empty.
Choose any node as root node.
Point arrows along edges in $T$, away from root node.
Add new arrows to $D T$.
Repeat this until $D T$ has $n-1$ elements:
Point arrows along edges in $T$, away from leaf nodes of current $D T$. Add new arrows to $D T$.

Figure 8.1: Example of finding MST (maximum spanning tree)

Figure 8.2: Example of giving directions to edges of spanning tree.

Nodes in a Chow-Liu tree can be rated in terms of their relative importance. Here are 2 possible metrics for measuring the importance of a node $\underline{a}$ :

$$
\begin{equation*}
N_{n b}(\underline{a})=\text { number of neighbors of } \underline{a} \tag{8.21}
\end{equation*}
$$

[^4]\[

$$
\begin{equation*}
\operatorname{traffic}(\underline{a})=\sum_{\underline{n} \in n b(\underline{a})} H(\underline{a}: \underline{n}) \tag{8.22}
\end{equation*}
$$

\]

For example, to get a tree with low depth, one can choose as the root node the node which has largest $N_{n b}$, and if there are several with the same largest $N_{n b}$, choose out of those the one with the largest traffic.

### 8.2 Tree Augmented Naive Bayes (TAN)

Recall from Chapter 34 that a Naive Bayes bnet consists of a class node $\underline{c}$ with $n$ children nodes $\underline{x}^{n}$, called the feature nodes. A Tree Augmented Naive Bayes (TAN) bnet is a Naive Bayes bnet with a tree grafted onto it like a chimera. More precisely, one starts with a Naive Bayes bnet and adds arrows between the feature nodes. The arrows are added in such a way that the TAN bnet sans node $\underline{c}$ constitutes a tree. It's not the most well motivated bnet in human history, but at least it adds a bit of correlation between the feature nodes of the Naive Bayes bnet. Those nodes are independent at fixed $\underline{c}$ in the Naive Bayes bnet, but are no longer so in the TAN bnet. See Figs 8.3 and 8.4 for an example of a TAN bnet.

Figure 8.3: bnet for Naive Bayes with 4 feature nodes and another bnet for a tree made of the same feature nodes.

Figure 8.4: TAN bnet constructed by merging Naive Bayes bnet and tree bnet of Fig. 8.3.

The total probability distribution $P_{T A N}$ for a TAN bnet can be parameterized as follows.

$$
\begin{equation*}
P_{T A N}\left(x^{n}, c\right)=P_{T A N}(c) \prod_{i=0}^{n-1} P_{T A N}\left(x_{i} \mid x_{\mu(i)}, c\right) \tag{8.23}
\end{equation*}
$$

As with Chow Liu trees, we can attempt to find a TAN bnet whose total probability $P_{T A N}=P_{\underline{t}^{n}, \underline{c}}$ best approximates an a priori given probability distribution $P=P_{\underline{x}^{n}, \underline{\underline{c}}}$.

Note that
Claim 5

$$
\begin{equation*}
\underset{\mu}{\operatorname{argmin}} H\left(\underline{x}^{n}, \underline{c}\right)=\underset{\mu}{\operatorname{argmax}} \sum_{i} H\left(\underline{x}_{i}: \underline{x}_{\mu(i)} \mid \underline{c}\right) \tag{8.24}
\end{equation*}
$$

proof:

$$
\begin{align*}
H\left(\underline{x}^{n}, \underline{c}\right) & =-\sum_{x^{n}, c} P\left(x^{n}, c\right)\left[\ln P(c)+\sum_{i} \ln P\left(x_{i} \mid x_{\mu(i)}, c\right)\right]  \tag{8.25}\\
& =-\sum_{x^{n}, c} P\left(x^{n}, c\right)\left[\ln P(c)+\sum_{i} \ln \left(\frac{P\left(x_{i}, x_{\mu(i)} \mid c\right)}{P\left(x_{i} \mid c\right) P\left(x_{\mu\left(x_{i}\right)} \mid c\right)} P\left(x_{i} \mid c\right)\right)\right]  \tag{8.26}\\
& =\sum_{i} H\left(\underline{x}_{i}, \underline{c}\right)-\sum_{i} H\left(\underline{x}_{i}: \underline{x}_{\mu(i)} \mid \underline{c}\right) \tag{8.27}
\end{align*}
$$

## QED

Following the same line of reasoning that we followed for Chow-Liu trees, we conclude that:

If $D_{K L}\left(P \| P_{T A N}\right)$ is minimized over all $P_{T A N}$, then

1. $P_{T A N}$ inherits its TPM's from $P$, and
2. $P_{T A N}$ gets its structure, which is being parameterized by the function $\mu$, by maximizing the score defined by

$$
\begin{equation*}
\text { score }=\sum_{i} H\left(\underline{x}_{i}: \underline{x}_{\mu(i)} \mid \underline{c}\right) \tag{8.28}
\end{equation*}
$$

One can build a TAN bnet from empirical data as follows:
Calculate a Chow-Liu Tree for each $c \in S_{c}$. For each of those trees, create a TAN bnet, and calculate its score given by Eq. 8.28 . Keep the TAN bnet with the largest score.

## Chapter 9

## Counterfactual Reasoning

This chapter is mostly based on Ref.[27], a 2019 review of causality by Pearl.
This chapter assumes that the reader has read Chapter 13 on do-calculus and Chapter 27 on LDEN (linear deterministic systems with external noise).

### 9.1 The 3 Rungs of Causal AI

According to Judea Pearl, there are 3 rungs in the ladder of causal AI. These are (as I see them):

1. Observing Dumbly: Collecting data and fitting curves to it, without any plan designed to investigate Nature's causal connections.
2. Doing causal experiments: Doing experiments consciously designed to elucidate Nature's causal connections. Even cats do this!, but current AI doesn't.
3. Imagining counterfactual situations, Analogizing: Imagining gedanken experiments to further understand Nature's causal connections, and to decide what future courses of action are more likely to succeed, even if there is zero direct data for those courses of action. Making predictions based on zero direct data is a very Bayesian concern, well out of the purview of frequentists. Nevertheless, humans do such "analogizing" all the time to great advantage. It becomes possible if there is some indirect but similar data that can be transported (transplanted, applied) to the situation of interest.

Chapter 31 on message passing is about rung 1. Chapter 13 on do-calculus is about rung 2 . This chapter is dedicated to rung 3 .

### 9.2 Two kinds of intervention operators

In Chapter 13, we introduced a do operator $\rho_{\underline{x}=x}$ (this is our notation for what Pearl symbolizes by $d o(\underline{x})=x)$. The study of counterfactuals requires that we introduce a
new kind of intervention operator that we will call an imagine operator and denote by $\kappa_{\underline{x} \rightarrow \underline{a}}(x)$.

The 2 types of intervention operators are defined graphically in Fig. 9.1.

- The do operator $\rho_{\underline{x}=5}$ (called $\rho$ because it turns $\underline{x}$ into a root node) amputates the incoming arrows of node $\underline{x}$ and sets the TPM of the new root node $\underline{x}$ to a delta function $\delta(x, 5)$ (or some state of $\underline{x}$ other than 5 ). Sometimes it is convenient, rather than calling the new node $\underline{x}$ like the old one, to call it by the new name $\rho \underline{x}$.
- The imagine operator $\kappa_{\underline{x} \rightarrow \underline{b}}(5)$ (called $\kappa$ because it creates konstant nodes) operates on arrows unlike the $\rho$ operator which operates on nodes. $\kappa_{\underline{x} \rightarrow \underline{b}}(5)$ deletes arrow $\underline{x} \rightarrow \underline{b}$ and creates a new root node $\underline{x}^{\prime}$ and a new arrow $\underline{x}^{\prime} \rightarrow \underline{b}$. The TPM of the new node $\underline{x}^{\prime}$ is a delta function $\delta\left(x^{\prime}, 5\right)$ (or some state of $\underline{x}$ other than 5). Sometimes it is convenient, rather than calling the new node $\underline{x}^{\prime}$, to call it by the more explicit name $\kappa_{\underline{b}} \underline{x}$.

Now that we have both a do and an imagine operator, we realize, as Pearl did long ago, that we can create a do-imagine-calculus whose objective is to express probabilities such as $P\left(\underline{y} \mid \rho \underline{r}=r, \kappa_{\underline{b}} \underline{s}=s, t\right)$ in terms of observable probabilities that do not contain any $\bar{d}$ o or imagine operators in them. As with do-calculus, this reduction is not always possible, and we say a probability is identifiable if it can be reduced in that manner. Such a do-imagine-calculus has already been developed by Pearl and collaborators, but we won't discuss it in this chapter (perhaps we will discuss it in a future one).

Figure 9.1: Action of "do" operator $\rho_{\underline{x}=5}$ on node $\underline{x}$ and of "imagine" operator $\kappa_{\underline{x} \rightarrow \underline{b}}(5)$ on arrow $\underline{x} \rightarrow \underline{b}$.

### 9.3 Do operator for DEN diagrams

By the end of this chapter, the two kinds of intervention operators will be applied to DEN diagrams. Let us begin that journey by showing in this section how to apply the already familiar do operator to DEN diagrams.

Recall that the structural equations for a linear DEN, as given by Eq. 27.21) of Chapter 27, are:

$$
\begin{equation*}
\underline{x}=A \underline{x}+\underline{u} . \tag{9.1}
\end{equation*}
$$

Therefore,

$$
\begin{equation*}
\underline{x}=(1-A)^{-1} \underline{u} \tag{9.2}
\end{equation*}
$$

which can be represented for both linear and non-linear DEN diagrams by:

$$
\begin{equation*}
\underline{x}_{i}=x_{i}(\underline{u} .) \tag{9.3}
\end{equation*}
$$

If now we apply the operator $\rho_{\underline{a}=a}$ to the diagram described by the structural equations Eqs 9.1, we get the following new structural equations:

$$
\underline{x}_{i}^{*}= \begin{cases}\sum_{j<i} A_{i \mid j} \underline{x}_{j}^{*}+\underline{u}_{i} & \text { if } \underline{x}_{i} \neq \underline{a}  \tag{9.4}\\ a & \text { if } \underline{x}_{i}=\underline{a}\end{cases}
$$

where we are calling $\underline{x}_{i}^{*}$ the nodes of the DEN diagram post intervention.
Eqs.(9.4) can be expressed in matrix notation as follows. Define $\pi_{\underline{a}}$ to be the $n x \times n x$ matrix with all entries equal to zero except for the $\left(i_{0}, i_{0}\right)$ entry, which is 1 . And define $e_{\underline{a}}$ to be the column vector with all entries zero except for the $i_{0}{ }^{\prime}$ th one, which is 1 . Here $i_{0}$ is defined so that $\underline{x}_{i_{0}}=\underline{a}$. In other words, $\pi_{\underline{a}}$ and $e_{\underline{a}}$ are defined by

$$
\begin{equation*}
\left(\pi_{\underline{a}}\right)_{i, j}=\mathbb{1}\left(i=j, \underline{a}=\underline{x}_{i}\right) \tag{9.5}
\end{equation*}
$$

and

$$
\begin{equation*}
\left(e_{\underline{a}}\right)_{i}=\mathbb{1}\left(\underline{a}=\underline{x}_{i}\right), \tag{9.6}
\end{equation*}
$$

for $i, j \in\{0,1, \ldots, n x-1\}$. Next define

$$
\begin{gather*}
\pi_{!\underline{a}}=1-\pi_{\underline{a}}  \tag{9.7}\\
A^{*}=\pi_{!\underline{\underline{1}}} A \tag{9.8}
\end{gather*}
$$

and

$$
\begin{equation*}
\underline{u}_{!\underline{a}}=\pi_{!\underline{\underline{u}}} \underline{u} \tag{9.9}
\end{equation*}
$$

The effect of pre-multiplying the matrix $A$ and the column vector $\underline{u}$ by $\pi_{!\underline{a}}$ is to leave all rows intact except for the $i_{0}$ row, which is set to zero. Here $i_{0}$ is defined by $\underline{a}=\underline{x}_{i_{0}}$. Finally, using all of the variables just defined, we can express the structural equations of the linear DEN diagram, post intervention, as

$$
\begin{equation*}
\underline{x}^{*}=A^{*} \underline{x}^{*}+\underline{u}_{\underline{\underline{a}}}+a e_{\underline{a}} . \tag{9.10}
\end{equation*}
$$

Thus,

$$
\begin{equation*}
\underline{x}^{*}=\left(1-A^{*}\right)^{-1}\left(\underline{u}_{\underline{\underline{a}}}+a e_{\underline{a}}\right) . \tag{9.11}
\end{equation*}
$$

which can be represented for both linear and non-linear DEN diagrams by:

$$
\begin{equation*}
\underline{x}_{i}^{*}=x_{i}^{*}\left(\underline{u_{!}}, a\right) \tag{9.12}
\end{equation*}
$$

For any bnet,

$$
\begin{gather*}
P(\underline{y}=y \mid \underline{x}=x)=P_{G}(\underline{y}=y \mid \underline{x}=x)  \tag{9.13}\\
P(\underline{y}=y \mid \rho \underline{x}=x)=P_{\rho_{\underline{x}=x} G}(\underline{y}=y) \tag{9.14}
\end{gather*}
$$

Claim 6 For a non-linear DEN diagram,

$$
\begin{equation*}
P(y \mid \rho \underline{x}=x)=E\left[\delta\left[y, y\left(\underline{u}_{\underline{x}}, x\right)\right]\right] . \tag{9.15}
\end{equation*}
$$

proof:

$$
\begin{align*}
P(\underline{y}=y \mid \rho \underline{x}=x) & =P_{\rho_{\underline{x}}=x}(\underline{y}=y)  \tag{9.16}\\
& =\sum_{u_{!\underline{x}}} P\left(u_{!\underline{x}}\right) P_{\rho_{\underline{x}=x} G}\left(\underline{y}=y \mid u_{!\underline{x}}\right)  \tag{9.17}\\
& =\sum_{u_{!\underline{x}}} P\left(u_{!\underline{x}} \delta\left[y, y\left(u_{!\underline{x}}, x\right)\right]\right.  \tag{9.18}\\
& =E_{\underline{u_{!~}}}\left[\delta\left[y, y\left(u_{!\underline{x}}, x\right)\right]\right]  \tag{9.19}\\
& =E\left[\delta\left[y, y\left(\underline{u}_{!\underline{x}}, x\right)\right]\right] \tag{9.20}
\end{align*}
$$

## QED

Claim 7 For a nonlinear DEN diagram,

$$
\begin{equation*}
E[\underline{y} \mid \rho \underline{x}=x]=E\left[y\left(\underline{u}_{\underline{x}}, x\right)\right] . \tag{9.21}
\end{equation*}
$$

## proof:

$$
\begin{align*}
E[\underline{y} \mid \rho \underline{x}=x] & =\sum_{y} y P(\underline{y}=y \mid \rho \underline{x}=x)  \tag{9.22}\\
& =\sum_{y} y E\left[\delta\left[y, y\left(u_{!\underline{x}}, x\right)\right]\right]  \tag{9.23}\\
& =E\left[y\left(u_{\underline{x}}, x\right)\right] \tag{9.24}
\end{align*}
$$

## QED

For any bnet

$$
\begin{equation*}
P(y \mid \rho \underline{x}=x, z)=\frac{P(y, z \mid \rho \underline{x}=x)}{P(z \mid \rho \underline{x}=x)}=P_{\rho_{\underline{x}=x} G}(y \mid x, z) \tag{9.25}
\end{equation*}
$$

For a nonlinear DEN diagram,

$$
\begin{gather*}
P(y, z \mid \rho \underline{x}=x)=\sum_{u_{!\underline{x}}} P\left(u_{!\underline{\underline{x}}} \delta\left[y, y\left(u_{!\underline{x}}, x\right)\right] \delta\left[z, z\left(u_{!\underline{x}}, x\right)\right]\right.  \tag{9.26}\\
P(z \mid \rho \underline{x}=x)=\sum_{u_{!\underline{x}}} P\left(u_{\underline{\underline{x}}}\right) \delta\left[z, z\left(u_{!\underline{x}}, x\right)\right] . \tag{9.27}
\end{gather*}
$$

### 9.4 Mediation Analysis

In the previous section, we applied the do operator to DEN diagrams. Mediation analysis is a nice example which applies both do and imagine operators to DEN diagrams.

G

$G^{*}$

Figure 9.2: Graphs $G$ and $G^{*}$ are used to discuss mediation. In graph $G$, the exogenous variables are independent, whereas in graph $G^{*}$ they are not.

The term "mediation analysis" refers to the analysis of the DEN diagram $G$ in Fig 9.2 . In that diagram, node $\underline{t}$ influences node $\underline{y}$ both directly and via the mediator node $\underline{m}$. The structural equations for that diagram are of the form:

$$
\begin{align*}
\underline{t} & =\underline{u}_{t}  \tag{9.28a}\\
\underline{m} & =f_{\underline{m}}\left(\underline{t}, \underline{u}_{\underline{m}}\right)  \tag{9.28b}\\
\underline{y} & =f_{\underline{y}}\left(\underline{t}, \underline{m}, \underline{u}_{\underline{y}}\right) \tag{9.28c}
\end{align*}
$$

Thus,

$$
\begin{equation*}
\underline{y}=f_{\underline{y}}\left(u_{\underline{t}}, f_{\underline{m}}\left(\underline{u_{\underline{t}}}, \underline{u}_{\underline{m}}\right), \underline{u}_{\underline{y}}\right) . \tag{9.29}
\end{equation*}
$$

$$
\rho_{\underline{t}=5} G \quad \kappa_{\underline{t} \rightarrow \underline{m}}(5) G
$$

Figure 9.3: Graph $G$ of Fig 9.2 after applying do operator $\rho_{\underline{t}=5}$ and imagine operator $\kappa_{\underline{t} \rightarrow \underline{m}}(5)$.

If we apply $\rho_{\underline{t}=5} G$ to Eqs. 9.28), we get

$$
\begin{align*}
\underline{t} & =5  \tag{9.30a}\\
\underline{m} & =f_{\underline{m}}\left(\underline{t}, \underline{u}_{\underline{m}}\right)  \tag{9.30b}\\
\underline{y} & =f_{\underline{y}}\left(\underline{t}, \underline{m}, \underline{u}_{\underline{y}}\right) \tag{9.30c}
\end{align*}
$$

Eqs 9.30 are represented graphically in Fig 9.3 . We will often denote the random variable $\underline{y}$ in Eqs. 9.30 by the more explicit symbol $\underline{y}_{\rho_{t=5} G}$. Pearl often refers to this $\underline{y}$ by the less explicit symbol $Y_{5}$ or $Y_{5}(u)$ where $Y=\underline{y}$ and $u=\left(u_{\underline{m}}, u_{\underline{y}}\right)=u_{!\underline{t}}$.

If we apply $\kappa_{\underline{t} \rightarrow \underline{m}}(5) G$ to Eqs. (9.28), we get

$$
\begin{align*}
\underline{t} & =\underline{u}_{t}  \tag{9.31a}\\
\underline{m} & =f_{\underline{m}}\left(5, \underline{u}_{\underline{m}}\right)  \tag{9.31b}\\
\underline{y} & =f_{\underline{y}}\left(\underline{t}, \underline{m}, \underline{u}_{\underline{y}}\right) \tag{9.31c}
\end{align*}
$$

Eqs 9.31 are represented graphically in $\operatorname{Fig} 9.3$. We will often denote the random variable $\underline{y}$ in Eqs. 9.31) by the more explicit symbol $\underline{y}_{\kappa_{\underline{t} \rightarrow \underline{m}}(5) G}$. Pearl often refers to this $\underline{y}$ by the less explicit symbol $Y_{5}$ or $Y_{5}(u)$ where $Y=\underline{y}$ and $u=\left(u_{\underline{t}}, u_{\underline{m}}, u_{\underline{y}}\right)$.

$$
\rho_{\underline{t}=t} G
$$

$$
\rho_{\underline{t}=t} \rho_{\underline{m}=m} G
$$

Figure 9.4: Graph $G$ of Fig 9.2 after applying the do operators $\rho_{\underline{t}=t}$ and $\rho_{\underline{t}=t} \rho_{\underline{m}=m}$.
Define the Total Effect (TE), and the Controlled Direct Effect (CDE) by

$$
\begin{align*}
T E & =E\left[\underline{y}_{\rho_{\underline{t}} G}-\underline{y}_{\rho_{\underline{t}}=0}\right]  \tag{9.32}\\
C D E(m) & =E\left[\underline{y}_{\rho_{\underline{t}=1} \rho_{\underline{m}=m} G}-\underline{y}_{\rho_{\underline{t}=0} \rho_{\underline{m}=m}}\right] \tag{9.33}
\end{align*}
$$

The two DEN diagrams $\rho_{\underline{t}=t} G$ and $\rho_{\underline{t}=t} \rho_{\underline{m}=m} G$ used in the definitions of $T E$ and $C D E$ are given in Fig 9.4.

Figure 9.5: Graph $G$ of Fig 9.2 after applying the imagine operator $\kappa$ to arrows $\underline{t} \rightarrow \underline{m}$ and $\underline{t} \rightarrow \underline{y}$.

Let

$$
\begin{equation*}
\mathcal{Y}_{a}^{b}=E\left[\underline{y}_{\kappa_{\underline{t} \underline{\underline{y}}}(a) \kappa_{\underline{t} \rightarrow \underline{m}}(b) G}\right] \tag{9.34}
\end{equation*}
$$

Fig 9.5 shows the diagram $\kappa_{\underline{t} \rightarrow \underline{y}}(a) \kappa_{\underline{t} \rightarrow \underline{m}}(b) G$ used in the definition of $\mathcal{Y}_{a}^{b}$.
Now define the Natural Direct Effect (NDE), and the Natural Indirect Effect (NIE) by

$$
\begin{align*}
N D E & =\mathcal{Y}_{1}^{0}-\mathcal{Y}_{0}^{0}  \tag{9.35}\\
N I E(t) & =\mathcal{Y}_{t}^{1}-\mathcal{Y}_{t}^{0} \tag{9.36}
\end{align*}
$$

Note that

$$
\begin{align*}
N D E+N I E(1) & =\left(\mathcal{Y}_{1}^{0}-\mathcal{Y}_{0}^{0}\right)+\left(\mathcal{Y}_{1}^{1}-\mathcal{Y}_{1}^{0}\right)  \tag{9.37}\\
& =\mathcal{Y}_{1}^{1}-\mathcal{Y}_{0}^{0}  \tag{9.38}\\
& =T E . \tag{9.39}
\end{align*}
$$

## Chapter 10

## Decision Trees

This chapter is based mainly on Ref. [36].

Figure 10.1: Example of dtree taken from Ref.[36]
Fig 10.1 shows a typical decision tree (dtree). This example was taken from Ref.[36], where it is analyzed in detail. As you can see, a dtree contains two main types of nodes: the non-leaf, internal nodes, and the leaf nodes. The internal nodes pose questions. In general, the answers ${ }^{1}$ to those questions can be multiple choices with two or more choices. For each of those choices, a tree branch labeled by the choice comes down from the question node. The leaf nodes represent endpoints, goals, final conclusions, etc. Dtrees can be viewed as classifiers. They take in a large amount of information about a population and compress that information to just a few classes. If $S_{\underline{\underline{c}}}$ is the set of distinct leaf node labels, then we call each $c \in S_{\underline{\underline{c}}}$ a class of the classifier. In the case of Fig 10.1, $S_{\underline{c}}=\{$ False, True $\}$.

Dtrees can be used with probabilities attached to each node, or without probabilities (as a plain undirected graph(UG)). This is analogous to bnets, which can

[^5]

Figure 10.2: Fig 10.1 with generic labels.

Figure 10.3: Fig 10.2 converted to a bnet.
be used with probabilities attached to each node (as DAGs with TPMs specified for each node) or without probabilities (as plain DAGs). Dtrees differ from bnets in that their tree branches are labelled, whereas bnet arrows aren't labelled. Also, whereas the nodes of a bnet carry a matrix of probabilities (the TPM), the nodes of a dtree carry just a column vector of probabilities which represents a single probability distribution. Henceforth, we will refer to the column vector of probabilities carried by each node of a dtree as its Transition Probability Vector (TPV). Without the TPVs, a dtree can be used as a deterministic classifier, to classify inputs. With the TPVs, it can be used as a probabilistic sampler (to generate random samples.)

### 10.1 Transforming a dtree into a bnet

A trivial observation that is seldom made in the dtree pedagogical literature is that every dtree maps into a special bnet, let's call it its "image" bnet, in a very natural way. We use the dtree of Fig 10.1 as an example to show how to do this. As a first

| $P(x \mid a)$ | $a=a_{0}$ | $a \in S_{\underline{a}}^{-}-\left\{a_{0}\right\}$ | null |
| :--- | :--- | :--- | :--- |
| 0 | $p_{0}$ | 0 | 0 |
| 1 | $p_{1}$ | 0 | 0 |
| $\vdots$ | $\vdots$ | 0 | 0 |
| $N_{\underline{x}}^{-}-1$ | $p_{N_{\underline{x}}-1}$ | 0 | 0 |
| null | 0 | 1 | 1 |

Table 10.1: TPM of a node of a dtree image bnet.
step, we go from Fig 10.1 to Fig 10.2 by replacing all the labels of the nodes and of the branches of the dtree by generic symbols. Next, we go from Fig. 10.2 to Fig. 10.3 , by replacing all tree branches by arrows pointing down, and by moving the tree branch labels down so that they become a suffix to the question that the tree branch leads to. At this point, we have created Fig. 10.3 , which constitutes the DAG of the image bnet. It remains for us to define a TPM for each node of this DAG.

Table 10.1 gives the TPM $P(x \mid a)$ for a node $\underline{x}$ with single parent $\underline{a}$ of a dtree image bnet. Say node $\underline{x}$ has a set $S_{x}^{-}$of possible tree branches coming out of it. Let $N_{\underline{x}}^{-}=\left|S_{\underline{x}}^{-}\right|$. Let $S_{\underline{x}}=S_{\underline{x}}^{-} \cup\{n u l l\}$ and $N_{\underline{x}}=\left|S_{\underline{x}}\right|=N_{\underline{x}}^{-}+1$. Define $S_{\underline{a}}^{-}, N_{\underline{a}}^{-}, S_{\underline{a}}$ and $N_{\underline{a}}$ analogously for node $\underline{a}$. In Table 10.1, $S_{\underline{x}}^{-}=\left\{0,1, \ldots, N_{\underline{x}}^{-}-1\right\}$ and $a_{0}$ is the value of node $\underline{a}$ which labels the tree branch connecting nodes $\underline{a}$ and $\underline{x} . \vec{p}=\left(p_{0}, p_{1}, \ldots, p_{N_{\underline{x}}-1}\right)$ is a probability distribution associated with node $\underline{x}$, its TPV. TPVs can be learned from a dataset following the dtree Structure Learning (SL) algorithm discussed in Section 10.2,

Table 10.1 also applies when node $\underline{x}$ is a leaf node, except that for leaf nodes, $\vec{p}$ is one hot (i.e., all components are zero except for one component which is 1 ). Also, all leaf nodes $\underline{x}$ have the same $S_{\underline{x}}^{-}$, namely $S_{\underline{\underline{c}}}$.

Adding a null state to the set of states (SOS) of each node of the image bnet is necessary because, once null is added to the SOS of any node, it must be added to the SOS of all descendant nodes. null must be added to the SOS of the children of the root node to take care of the situations when those first children don't receive the state they were expecting from their parent, i.e., the root node.

When drawing dtrees, some people put info like explanations and probabilities on the branches of the dtree. That info can all be preserved in the TPM and the node names and node state names of the image bnet nodes. One can also place info inside tool tips attached to the node name and node state names. Often, the pedagogical literature states that dtrees are more explicit and carry more info than their image bnets, but if one follows the above prescriptions, both can carry the same info.

A naive Bayes (NB) bnet (see Chapter 34) consists of a single "class node" with states $S_{c}$ that fans out with arrows pointing to the "feature nodes". If each leaf node of a NB bnet fans out into a set of new leaf nodes, and those new leaf nodes also fan out and so on, we get a generalized NB bnet. Let's call this type of tree bnet an $N B^{*}$ bnet. An $N B^{*}$ bnet has the same graph structure as the image bnet of a dtree,
but it's more general, because its TPMs are more general. Each TPM of a $N B^{*}$ bnet can have several non-trivial columns instead of just one $\mathrm{TPV}=\vec{p}$.

### 10.2 Structure Learning for Dtrees

Let
$J_{0}=\{0,1, \ldots, n j-1\}$
$\Sigma=\{0,1,2, \ldots$, nsam -1$\}$
$D S=\left\{\left(\sigma, x^{\sigma}, c^{\sigma}\right): \sigma \in \Sigma\right\}$ be a dataset
$\sigma \in \Sigma$ be an individual (a sample) from a population (sampling set),
$x^{\sigma} \in S_{\underline{x}}$ be the feature (attributes, questions) vector. $S_{\underline{x}}=S_{\underline{x}_{0}} \times S_{\underline{x}_{1}} \times$ $\ldots \times S_{\underline{x}_{n j-1}}, x=\left(x_{0}, x_{1}, \ldots, x_{n j-1}\right) \in S_{\underline{x}}, x_{j} \in S_{\underline{x}_{j}}$
$c^{\sigma} \in S_{\underline{c}}$ be a classification class
We will assume $\Sigma, S_{\underline{x}}$ and $S_{\underline{c}}$ are finite sets.
Building a classifier $f$ for a dtree means finding a deterministic function $f: S_{\underline{x}} \rightarrow S_{\underline{c}}$ such that $c^{\sigma} \approx f\left(x^{\sigma}\right)$ for all $\sigma \in \Sigma$. If we divide the population $\Sigma$ into two large disjoint sets, a training set $\Sigma_{\text {train }}$ and a validation set $\Sigma_{\text {vali }}$, and if $c^{\sigma} \approx f\left(x^{\sigma}\right)$ very closely for $\sigma \in \Sigma_{\text {train }}$ but fits poorly for $\sigma \in \Sigma_{\text {vali }}$, then we say the classifier (curve fit) $f$ suffers from overfitting. We can learn the structure and TPVs of a dtree from a dataset $D S$, by using the dtree Structure Learning (SL) algorithm that we will discuss in detail later. However, that algorithm is prone to produce a classifier $f$ that overfits. Two techniques commonly used to reduce the effects of overfitting are pruning and Random Forests (RF). Pruning just means somehow removing nodes that are too specific. RFs are ensembles of dtrees that one averages over. In this chapter, we will only deal with a single dtree, not an ensemble of them.

Below, we give the standard algorithm for SL of a dtree, in the form of pseudocode. But first, we define two quantities, Information Gain and Gini, that are used in that pseudo-code.

### 10.2.1 Information Gain, Gini

This section uses various Shannon Information Theory entropies. Our notation for those entropies is described in Chapter Notational Conventions and Preliminaries on Notational Conventions.

Call a separation ability measure (SAM) a measure used to decide, when constructing a dtree from a dataset, in what order to ask the questions about the feature vector $x$. The question order is decided by searching over all so far unused questions for the question with the largest SAM. $\square^{2}$

[^6]
\[

$$
\begin{array}{cc}
\left\{N_{j}(c)\right\}_{c \in S_{\underline{c}}}\left\{N_{k}(c)\right\}_{c \in S_{\underline{c}}} \\
\sum_{c \in S_{\underline{c}}} N_{j}(c)=N_{j} & \sum_{c \in S_{\underline{c}}} N_{k}(c)=N_{k} \\
\sum_{k \in c h(j)} N_{k}(c)=N_{j}(c)
\end{array}
$$
\]

Figure 10.4: Some population numbers associated with the nodes of a dtree. $N_{j}(c)$ is the number of individuals $\sigma$ in the population that reaches node $j$ and belongs to class $c . \operatorname{ch}(j)$ is the set of nodes $k$ that are children of node $j$.

$$
\underline{j} \longrightarrow \underline{k} \longrightarrow \underline{c}
$$

Figure 10.5: Bnet derived from population numbers in Fig 10.4
Fig 10.4 defines some population numbers associated with the nodes of a dtree. From these population numbers, we can define the bnet in Fig. 10.5 . The TPMs, printed in blue, for the (non-root) nodes of this bnet, are as follows

$$
\begin{gather*}
P(c \mid k)=\frac{N_{k}(c)}{N_{k}}  \tag{10.1}\\
P(k \mid j)=\frac{N_{k}}{N_{j}} \mathbb{1}(k \in c h(j)) \tag{10.2}
\end{gather*}
$$

where $j, k \in J_{0}$ are dtree nodes, $c \in S_{\underline{c}}$ is a class node, and $c h(j)$ is the set of nodes $k$ that are children of node $j$.

Note that

$$
\begin{align*}
\sum_{k \in c h(j)} P(c \mid k) P(k \mid j) & =\sum_{k \in c h(j)} \frac{N_{k}(c)}{N_{k}} \frac{N_{k}}{N_{j}}  \tag{10.3}\\
& =\frac{N_{j}(c)}{N_{j}}  \tag{10.4}\\
& =P(c \mid j) \tag{10.5}
\end{align*}
$$

so these TPMs are consistent with the Markov-chain bnet structure shown in Fig 10.5 .

## Claim 8

$$
\begin{equation*}
\sum_{k} H(\underline{c} \mid k) P(k \mid j)=H(\underline{c} \mid \underline{k}, j) \tag{10.6}
\end{equation*}
$$

for the Markov chain $\underline{c} \leftarrow \underline{k} \leftarrow \underline{j}$.
proof:

$$
\begin{align*}
\sum_{k} H(\underline{c} \mid k) P(k \mid j) & =-\sum_{c} \sum_{k} P(c \mid k) P(k \mid j) \ln P(c \mid k)  \tag{10.7}\\
& =-\sum_{c} \sum_{k} P(c \mid k) P(k \mid j)\{\ln [P(c \mid k) P(k \mid j)]-\ln P(k \mid j)\}  \tag{10.8}\\
& =-\sum_{c} \sum_{k} P(c, k \mid j) \ln P(c, k \mid j)-H(\underline{k} \mid j)  \tag{10.9}\\
& =H(\underline{c}, \underline{k} \mid j)-H(\underline{k} \mid j)  \tag{10.10}\\
& =H(\underline{c} \mid \underline{k}, j) \tag{10.11}
\end{align*}
$$

## QED

One can define the following information theory quantities associated with bnet Fig 10.5.

$$
\begin{align*}
& I N F O_{-} f i n_{j}=-\sum_{c} P(c \mid j) \ln P(c \mid j)  \tag{10.12}\\
& =H(\underline{c} \mid j)  \tag{10.13}\\
& \text { INFO_init }{ }_{j}=\sum_{k \in c h(j)} P(k \mid j) H(\underline{c} \mid k)  \tag{10.15}\\
& =H(\underline{c} \mid \underline{k}, j) \quad \text { (using Claim 8) }  \tag{10.16}\\
& \text { INFO_gain }=\text { INFO_fin }- \text { INFO_init }{ }_{j}  \tag{10.17}\\
& =H(\underline{c} \mid j)-H(\underline{c} \mid \underline{k}, j)  \tag{10.18}\\
& =H(\underline{c}: \underline{k} \mid j)
\end{align*}
$$

The mutual information $H(\underline{c}: \underline{k} \mid j)$ is usually called the information gain for node $\underline{x}_{j}$. Maximizing this mutual information produces a node $k$ that has a large correlation
to a class $c$ for each $k \in \operatorname{ch}(j)$. If the goal is to reach a point where each leaf node is closely correlated to a different class, then maximizing the Information Gain of each new node is a greedy move towards that goal. Thus, Information Gain is a good (in fact, the preferred) SAM for dtree SL.

Call

$$
\begin{equation*}
H(\underline{c} \mid j)=-\sum_{c \in S_{\underline{c}}} P(c \mid j) \ln P(c \mid j) \tag{10.20}
\end{equation*}
$$

the class-entropy for node $\underline{x}_{j}$.
Note that if we approximate

$$
\begin{align*}
\ln P(c \mid j) & \approx \ln [1+P(c \mid j)-1]  \tag{10.21}\\
& \approx P(c \mid j)-1 \tag{10.22}
\end{align*}
$$

in Eq. 10.20 , we get what is usually called the Gini for node $\underline{x}_{j}$ :

$$
\begin{equation*}
\text { Gini }_{j}=1-\sum_{c \in S_{\underline{c}}} P(c \mid j)^{2} \tag{10.23}
\end{equation*}
$$

$G i n i_{j}$ is a simpler to compute polynomial approximation to $H(\underline{c} \mid j)$.
One can also define a Gini gain for node $\underline{x}_{j}$ by approximating Eq. 10.19) for $I N F O \_$gain $_{j}$.

$$
\begin{equation*}
\text { Gini_gain }_{j}=\sum_{c, k} \frac{P(c \mid k, j)^{2} P(k \mid j)}{P(c \mid j)}-1 \tag{10.24}
\end{equation*}
$$

We say a probability distribution $P_{\underline{x}}$, is pure (i.e., deterministic) if $P_{\underline{x}}(x)=$ $\delta\left(x, x_{0}\right)$. Gini $_{j}$ and $H(\underline{c} \mid j)$ are both always non-negative. They both vanish iff $P(c \mid j)$ is pure. Thus, $G i n i_{j}$ and $H(\underline{c} \mid j)$ are both good measures of class impurity.

### 10.2.2 Pseudo-code

Below, we give the standard algorithm for SL of a dtree, in the form of pseudo-code. The strategy employed by the algo is to assume an incoming population into the current root node, then determine the feature $x_{j}$ that best separates that incoming population. The feature $x_{j}$ is chosen so as to maximize Information Gain or Gini. This process is repeated by nominating the end of each new branch to be the current root node. In essence, what we are doing is performing a top-down, greedy search through the space of possible dtrees.

The algo in the pseudo-code below is called ID3 (Iterative Dichotomiser 3) or CART (Classification and Regression Trees). ID3 (Quinlan, 1986) and CART (Breiman et al, 1984) are almost identical, but were invented independently. As you
can see, ID3/CART is quite old. Many in the AI community consider it old fashioned compared to neural nets.

The pseudo-code below uses the majority function defined in Chapter Notational Conventions and Preliminaries,

```
Algorithm 1: Pseudo-code for learning a dtree from a dataset
    Input : dataset \(D S=\left\{\left(\sigma, x^{\sigma}, c^{\sigma}\right): \sigma \in \Sigma\right\}\),
            set of classification classes \(S_{\underline{c}}\),
            set of currently available node indices \(J\), where \(J \subset J_{0}\)
    Output: tree \(T\),
            population numbers \(\left\{\left(j, c, N_{j}(c)\right): j \in J_{0}, c \in S_{\underline{c}}\right\}\) stored globally
    \(J \leftarrow J_{0}\)
    Function learn_dtree \(\left(D S, S_{\underline{c}}, J\right)\) :
        \(\Sigma \leftarrow\) set of all \(\sigma\) in \(D S\)
        if \(\left\{c^{\sigma}: \sigma \in \Sigma\right\}=\{c\}\) then
            \(T \leftarrow\) one node tree with leaf node label \(=c\)
        else if \(J=\emptyset\) then
            \(T \leftarrow\) one node tree with leaf node label= majority \(\left(\left[c^{\sigma}: \sigma \in \Sigma\right]\right)\)
        else
            \(r \leftarrow \operatorname{argmax} I N F O \_\)gain \(_{j}(D S)\)
            from \(D S\), calculate \(\left\{\left(r, c, N_{r}(c)\right): c \in S_{\underline{c}}\right\}\) and store it globally
            \(T \leftarrow\) a new decision tree with root node \(\underline{x}_{r}\)
            for \(v \in S_{\underline{x}_{r}}\) do
            add a branch to tree \(T\) below \(\underline{x}_{r}\) with label " \(\underline{x}_{r}=v\) "
            \(D S_{1} \leftarrow\) subset of \(D S\) with \(\underline{x}_{r}=v\)
            if \(D S_{1}=\emptyset\) then
            below the new branch add a
            leaf node labeled \(=\operatorname{majority}\left(\left[c^{\sigma}: \sigma \in \Sigma\right]\right)\)
        else
            below the new branch add
            subtree \(=\) learn_dtree \(\left(D S_{1}, S_{\underline{x}}, J-\{j\}\right)\)
```

    return \(T\)
    
## Chapter 11

## Difference-in-Differences

This chapter is based on Ref. [3].
The Difference-in-Differences (DID) method was first used by John Snow in an 1854 report that argued that cholera in London was being transmitted by sewage polluted water rather than, as others at the time believed, by air (in fetid vapors called miasmas). In general, one can apply DID to discover causal effects in historical data. By historical data (aka a natural experiment. See Ref.[73]) we mean data that is collected long after the treatment (rather than during it) and is thus not subject to active intervention by the experimenter.

This chapter assumes that the reader has read Chapter 39 on Potential Outcomes (PO). The DID method applies the basic single-time PO theory described in Chapter 39, to 2 well separated times in which different conditions prevail.

### 11.1 John Snow, DID and a cholera transmission pathway

Let

$$
\begin{aligned}
& d \in\{0,1\} \\
& t \in\left\{t_{0}, t_{1}\right\}, t_{0}<t_{1} \\
& y=f(d, t) \in \mathbb{R} . \\
& \text { Define }
\end{aligned}
$$

$$
\begin{gather*}
\Delta_{t} f(d, t)=f\left(d, t_{1}\right)-f\left(d, t_{0}\right)  \tag{11.1}\\
\Delta_{d} f(d, t)=f(1, t)-f(0, t)  \tag{11.2}\\
D I D=\delta=\Delta_{d} \Delta_{t} f(d, t) \tag{11.3}
\end{gather*}
$$

DID is illustrated in Fig 11.1 .

Figure 11.1: Pictorial representation of Difference-in-differences (DID) as a difference of two differences (i.e., a difference of two slopes).

A time series is any function of time for which the domain is a discrete set of times.

In DID, one calculates the slope, over the same time interval, of two time series. One of the time series $(d=0)$ is for the control (i.e., untreated) population and the other $(d=1)$ is for the treated population. Then the difference $\delta$ of those 2 slopes is taken. The idea is that if there is no causal difference between the 2 time series, then both time series will have the same slope, and $\delta$ will be zero.

Figure 11.2: $D I D=\delta$ expressed as a a triple vector product.
Note that, as shown Fig 11.2, $D I D=\delta$ can also be expressed as a triple vector product. Indeed, consider a space of points $(t, y, z) \in \mathbb{R}^{3}$ with an orthonormal basis $\hat{t}, \hat{y}, \hat{z}$. Let $\Delta t=t_{1}-t_{0}$. Let $m_{d}$ be the slope of the lines $d \in\{0,1\}=\{$ untreated, treated \}. Let

$$
\begin{equation*}
\vec{r}_{d}=\left(\Delta t, m_{d} \Delta t, 0\right) \tag{11.4}
\end{equation*}
$$

for $d \in\{0,1\}$. Then

$$
\begin{align*}
\frac{1}{\Delta t} \vec{r}_{0} \times \vec{r}_{1} \cdot \hat{z} & =\frac{1}{\Delta t} \operatorname{det}\left[\begin{array}{ccc}
\Delta t & m_{0} \Delta t & 0 \\
\Delta t & m_{1} \Delta t & 0 \\
0 & 0 & 1
\end{array}\right]  \tag{11.5}\\
& =\left(m_{1}-m_{0}\right) \Delta t  \tag{11.6}\\
& =\delta \tag{11.7}
\end{align*}
$$

When $\vec{r}_{0}$ and $\vec{r}_{1}$ are parallel, $\vec{r}_{0} \times \vec{r}_{1}=0$ so $\delta=0$.

|  | $t=t_{0}(1849)$ | $t=t_{1}(1854)$ |
| :---: | :---: | :---: |
| $\tilde{d}=1($ town 1) | 85 deaths, polluted DW | 19 deaths, unpolluted DW |
| $\tilde{d}=0($ town 0) | 135 deaths, polluted DW | 147 deaths, polluted DW |

Table 11.1: A condensation of the data collected by John Snow in 1854, to test the hypothesis that cholera in London was being spread by polluted drinking water (DW).

A condensation of the data collected by John Snow in 1854 is given in Table 11.1. From that data, we find that

$$
\begin{equation*}
\delta=\Delta_{d} \Delta_{t} f(d, t)=(19-85)-(147-135)=-66-12=-78 \tag{11.8}
\end{equation*}
$$

### 11.2 PO analysis

In this section, we show how to analyze the DID method using the formalism of PO theory.

We will speak of a treatment outcome $\underline{y}_{t, g^{\sigma}}^{\sigma}\left(\underline{d}^{\sigma}, \underline{x}^{\sigma}\right)$ for individual $\sigma$ that depends, not just on the treatment dose $d^{\sigma} \in\{0,1\}$ and the confounder state $\underline{x}^{\sigma}$, but also on a group parameter (i.e., which population or town) $g^{\sigma} \in\{0,1\}$ and on a time parameter $t \in\left\{t_{0}, t_{1}\right\}$ (note $t$ is independent of $\sigma$ ). Actually, we will assume $g^{\sigma}=d^{\sigma}$, so we will just speak of $\underline{y}_{t}^{\sigma}\left(\underline{d}^{\sigma}, \underline{x}^{\sigma}\right)$ with no explicit $g^{\sigma}$ dependence. As usual for PO theory, we will consider expected values of $y_{t}^{\sigma}$ :

$$
\begin{equation*}
E_{\sigma \mid \tilde{d}, x}\left[y_{t}^{\sigma}(d)\right]=E_{y_{t} \mid \tilde{d}, x}\left[\underline{y}_{t}(d)\right]=\mathcal{Y}_{d \mid \tilde{d}, x}(t) \tag{11.9}
\end{equation*}
$$

To calculate these expected values, we need a "model" with probability distributions. In this case, the needed model and probability distributions are provided by the bnets depicted in Fig 11.3. The TPMs, printed in blue, for the bnet $G_{t, i m}$ in Fig 11.3, are as follows. Note that the TPMs for the bnet $G_{t, i m}$ are defined in terms of the TPMs for the bnet $G_{t}$.

Figure 11.3: $t \in\left\{t_{0}, t_{1}\right\}$. Bnet $G_{t, i m}=\kappa_{\underline{d}^{\sigma} \rightarrow \underline{y}_{t}^{\sigma}}\left(\tilde{d}^{\sigma}\right) G_{t}$ is obtained by applying the imagine operator to arrow $\underline{d}^{\sigma} \rightarrow \underline{y}_{t}^{\sigma}$ of bnet $G_{t}$.

$$
\begin{gather*}
P\left(x^{\sigma}\right)=P_{\underline{x}}\left(x^{\sigma}\right)  \tag{11.10}\\
P\left(d^{\sigma} \mid x^{\sigma}\right)=P_{\underline{d} \mid \underline{x}}\left(d^{\sigma} \mid x^{\sigma}\right)  \tag{11.11}\\
P\left(y_{t}^{\sigma} \mid \tilde{d}^{\sigma}, x^{\sigma}\right)=P_{\underline{y}_{t} \mid \underline{d}, \underline{x}}\left(y_{t}^{\sigma} \mid \tilde{d}^{\sigma}, x^{\sigma}\right)  \tag{11.12}\\
P\left(\left(\tilde{d}^{\sigma}\right)^{\prime}\right)=\delta\left(\left(\tilde{d}^{\sigma}\right)^{\prime}, \tilde{d}^{\sigma}\right) \tag{11.13}
\end{gather*}
$$

Figure 11.4: Four different time-dependent expected values $\mathcal{Y}_{d \mid \tilde{d}}(t)$ of $y_{t}^{\sigma}$ for bnet $G_{t, i m}$ The 4 magenta stars represents the 4 DID measurements.

Henceforth, for simplicity, we will omit the confounder state $x$ from the indices of $\mathcal{Y}$; i.e., we will write $\mathcal{Y}_{d \mid \tilde{d}}(t)$ instead of $\mathcal{Y}_{d \mid \tilde{d}, x}(t)$. The fact that we will not explicitly
mention $x$ does not mean that it doesn't exist or that it doesn't affect our analysis. John Snow does not seem to have considered any confounders in his cholera study, or else he tried to collect data restricted to a single stratum $x$. If there are confounders, they cannot be neglected. As discussed in Chapter 39 under the subject of stratamatching in PO, one must condition $\mathcal{Y}$ on a single $x$ stratum and, later on, one must average over all the possible $x$ strata.

Let $\mathcal{M} \mathcal{Y}_{d \mid \tilde{d}}(t)$ denote the measured $\mathcal{Y}_{d \mid \tilde{d}}(t)$. We define this quantity as

$$
\begin{equation*}
\mathcal{M} \mathcal{Y}_{d \mid \tilde{d}}(t)=\mathcal{Y}_{d \mid \tilde{d}}(t)\left[\mathbb{1}\left(d=0, t=t_{0}\right)+\mathbb{1}\left(d=\tilde{d}, t=t_{1}\right)\right] \tag{11.14}
\end{equation*}
$$

Now we claim that the DID $\delta$ calculated in the previous section for John Snow's data, can be expressed in PO formalism as follows:

$$
\begin{equation*}
\delta=\Delta_{\tilde{d}} \Delta_{t} \sum_{d} \mathcal{M} \mathcal{Y}_{d \mid \tilde{d}}(t) \tag{11.15}
\end{equation*}
$$

Fig. 11.4 depicts the four functions $\mathcal{Y}_{d \mid \tilde{d}}(t)$ for $t$ in the interval $\left[t_{0}, t_{1}\right]$ and for $d, \tilde{d} \in$ $\{0,1\}$. The $\mathcal{Y}$ coordinates of the four magenta stars in Fig 11.4 can be calculated using bnet $G_{t}$.

Define the parallel trends (PT) by

$$
\begin{equation*}
P T=\Delta_{\tilde{d}} \Delta_{t} \mathcal{Y}_{0 \mid \tilde{d}}(t) \tag{11.16}
\end{equation*}
$$

We will say the parallel trends assumption (PTA) holds if $P T=0$.
Next we prove that the DID $\delta$ equals the sum of an ATT ${ }^{\square}$ and PT.

$$
\begin{align*}
\delta & =\Delta_{\tilde{d}} \Delta_{t} \sum_{d} \mathcal{M}_{\mathcal{Y}_{d \mid \tilde{d}}(t)}  \tag{11.17}\\
& =\sum_{d}\left[\Delta_{t} \mathcal{M} \mathcal{Y}_{d \mid 1}(t)-\Delta_{t} \mathcal{M} \mathcal{Y}_{d \mid 0}(t)\right]  \tag{11.18}\\
& =\sum_{d}\left[\mathcal{M} \mathcal{Y}_{d \mid 1}\left(t_{1}\right)-\mathcal{M} \mathcal{Y}_{d \mid 1}\left(t_{0}\right)\right]-\sum_{d}\left[\Delta_{t} \mathcal{M} \mathcal{Y}_{d \mid 0}\left(t_{1}\right)-\Delta_{t} \mathcal{M} \mathcal{Y}_{d \mid 0}\left(t_{0}\right)\right]  \tag{11.19}\\
& =\mathcal{Y}_{1 \mid 1}\left(t_{1}\right)-\mathcal{Y}_{0 \mid 1}\left(t_{0}\right)-\left\{\mathcal{Y}_{0 \mid 0}\left(t_{1}\right)-\mathcal{Y}_{0 \mid 0}\left(t_{0}\right)\right\}  \tag{11.20}\\
& =\mathcal{Y}_{1 \mid 1}\left(t_{1}\right)-\mathcal{Y}_{0 \mid 1}\left(t_{0}\right)-\left\{\mathcal{Y}_{0 \mid 0}\left(t_{1}\right)-\mathcal{Y}_{0 \mid 0}\left(t_{0}\right)\right\}+\underbrace{\left\{\mathcal{Y}_{0 \mid 1}\left(t_{1}\right)-\mathcal{Y}_{0 \mid 1}\left(t_{1}\right)\right\}}_{\text {zero }}  \tag{11.21}\\
& =\underbrace{\mathcal{Y}_{1 \mid 1}\left(t_{1}\right)-\mathcal{Y}_{0 \mid 1}\left(t_{1}\right)}_{A T T\left(t_{1}\right)}-\mathcal{Y}_{0 \mid 1}\left(t_{0}\right)-\left\{\mathcal{Y}_{0 \mid 0}\left(t_{1}\right)-\mathcal{Y}_{0 \mid 0}\left(t_{0}\right)\right\}+\mathcal{Y}_{0 \mid 1}\left(t_{1}\right)  \tag{11.22}\\
& =A T T\left(t_{1}\right)-\Delta_{t} \mathcal{Y}_{0 \mid 0}(t)+\Delta_{t} \mathcal{Y}_{0 \mid 1}(t)  \tag{11.23}\\
& =A T T\left(t_{1}\right)+\underbrace{\Delta_{\tilde{d}} \Delta_{t} \mathcal{Y}_{0 \mid \tilde{d}}(t)}_{\text {zero if PTA holds }} \tag{11.24}
\end{align*}
$$

[^7]
### 11.3 Linear Regression

In this section, we show how to apply linear regression (LR) to the PO analysis of DID.

As before, let $y_{t}^{\sigma}(\tilde{d} \sigma)$ be the treatment outcome for individual $\sigma$, who receives a treatment dose $\tilde{d}^{\sigma}$ at times $t \in\left\{t_{0}, t_{1}\right\}$. $y_{t}^{\sigma}\left(\tilde{d}^{\sigma}\right)$ can be fitted as follows. Here $\epsilon^{\sigma}$ is the residual for individual $\sigma$ and $b_{0}, m_{0}, b_{1}, m_{1} \in \mathbb{R}$ are the fit parameters.

$$
\begin{equation*}
y_{t}^{\sigma}=\left[b_{0}+m_{0} t\right]\left(1-\tilde{d}^{\sigma}\right)+\left[b_{1}+m_{1} t\right] \tilde{d}^{\sigma}+\epsilon^{\sigma} . \tag{11.25}
\end{equation*}
$$

Note that Eq. 11.25 yields a straight line in the $y_{t}^{\sigma}-t$ plane for $d^{\sigma}=0$, and another straight line for $d^{\sigma}=1$. We are using the standard symbols $b$ to denote the y-intercept, and $m$ to denote the slope of a straight line.

Taking the expected value of Eq. (11.25), we get

$$
\begin{equation*}
\mathcal{Y}_{d \mid \tilde{d}}(t)=\left[b_{0}+m_{0} t\right](1-\tilde{d})+\left[b_{1}+m_{1} t\right] \tilde{d} \tag{11.26}
\end{equation*}
$$

with $d=0$ for $t=t_{0}$ and $d=\tilde{d}$ for $t=t_{1}$.
Let $\Delta t=t_{1}-t_{0}$. Since $\Delta_{t} t=\Delta t$ and $\Delta_{d} d=1$, one gets

$$
\begin{equation*}
\delta=\Delta_{d} \Delta_{t} \mathcal{M} \mathcal{Y}_{d \mid \tilde{d}}(t)=\Delta_{d} \Delta_{t} y_{t}^{\sigma}=\left(m_{1}-m_{0}\right) \Delta t \tag{11.27}
\end{equation*}
$$

Figure 11.5: We use Linear Regression to fit a straight line between points $S_{0}$ and $F_{0}$, and between points $S_{1}$ and $F_{1}$. ( $\mathrm{S}=$ starting, $\mathrm{F}=$ finishing $) . S_{0}, S_{1}, F_{0}, F_{1}$ are the measurement points. Point $I$ is an image of point $F_{0}$. Point $C$ is a counterfactual point.

|  | $t=t_{0}$ | $t=t_{1}$ |
| :---: | :---: | :---: |
| $\tilde{d}=1$ | $\mathcal{Y}\left(S_{1}\right)=\mathcal{Y}_{0 \mid 1}\left(t_{0}\right)$ | $\mathcal{Y}\left(F_{1}\right)=\mathcal{Y}_{1 \mid 1}\left(t_{1}\right)$ |
| $\tilde{d}=0$ | $\mathcal{Y}\left(S_{0}\right)=\mathcal{Y}_{0 \mid 0}\left(t_{0}\right)$ | $\mathcal{Y}\left(F_{0}\right)=\mathcal{Y}_{0 \mid 0}\left(t_{1}\right)$ |

Table 11.2: $\mathcal{Y}$ coordinates of points $S_{0}, S_{1}, F_{0}, F_{1}$ in Figs 11.4 and 11.5 .

Figs 11.4 and 11.5 define points $S_{0}, S_{1}, F_{0}, F_{1}, I, C$. The $\mathcal{Y}$ coordinates of points $S_{0}, S_{1}, F_{0}, F_{1}$ are given by Table 11.2. The $\mathcal{Y}$ coordinates of points $C, I$ are given by Eqs.11.28.

$$
\begin{gather*}
\mathcal{Y}(C)=\mathcal{Y}_{0 \mid 1}\left(t_{1}\right)  \tag{11.28a}\\
\mathcal{Y}(I)=\mathcal{Y}\left(F_{0}\right)+\left[\mathcal{Y}\left(S_{1}\right)-\mathcal{Y}\left(S_{0}\right)\right] \tag{11.28b}
\end{gather*}
$$

We can express $A T T$ and the $\delta$ for DID in terms of the $\mathcal{Y}$ of the points $S_{0}, S_{1}, F_{0}, F_{1}, I, C$. Indeed,

$$
\begin{align*}
\delta= & \mathcal{Y}\left(F_{1}\right)-\mathcal{Y}(I)  \tag{11.29}\\
= & \mathcal{Y}\left(F_{1}\right)-\mathcal{Y}\left(F_{0}\right)-\left[\mathcal{Y}\left(S_{1}\right)-\mathcal{Y}\left(S_{0}\right)\right]  \tag{11.30}\\
& A T T=\mathcal{Y}\left(F_{1}\right)-\mathcal{Y}(C) \tag{11.31}
\end{align*}
$$

Hence,

$$
\begin{equation*}
\delta=A T T \Longleftrightarrow \mathcal{Y}(I)=\mathcal{Y}(C) \Longleftrightarrow \text { PTA holds } \tag{11.32}
\end{equation*}
$$

## Chapter 12

## Digital Circuits

Figure 12.1: Typical digital circuit of NAND gates.
Digital (logic) gate: node with $n a$ input ports and $n x$ output ports which represents a function

$$
\begin{equation*}
f:\{0,1\}^{n a} \rightarrow\{0,1\}^{n x} \tag{12.1}
\end{equation*}
$$

Suppose
$a^{n a}=\left(a_{i}\right)_{i=0,1, \ldots, n a-1}$ where $a_{i} \in\{0,1\}$,
$x^{n x}=\left(x_{i}\right)_{i=0,1, \ldots, n x-1}$ where $x_{i} \in\{0,1\}$.
$f$ maps $a^{n a}$ into $x^{n x}$.
Digital circuit (dcircuit) $=$ circuit of digital gates.

Figure 12.2: 2 options for mapping dcircuit node with multiple output ports into bnet.

### 12.1 Mapping any dcircuit to a bnet

### 12.1.1 Option A of Fig. $\mathbf{1 2 . 2}$

1. Replace every dcircuit gate described by Eq. 12.1) by $n x$ bnet nodes $\underline{x}_{i}$ for $i=0,1, \ldots, n x-1$ such that

$$
\begin{equation*}
P\left(x_{i} \mid a^{n a}\right)=\delta\left(x_{i}, f_{i}\left(a^{n a}\right)\right) \tag{12.2}
\end{equation*}
$$

2. Replace all connectors of the dcircuit by arrows pointing in the direction of the bit flow.

### 12.1.2 Option B of Fig. $\mathbf{1 2 . 2}$

1. Replace every dcircuit gate described by Eq. (12.1) with one bnet node called $\underline{x}^{n x}$ and, if $n x>0, n x$ "marginalizer nodes" $\underline{m}_{i}$ for $i=0,1, \ldots, n x-1$, such that

$$
\begin{equation*}
P\left(x^{n x} \mid a^{n a}\right)=\delta\left(x^{n x}, f\left(a^{n a}\right)\right), \tag{12.3}
\end{equation*}
$$

and

$$
\begin{equation*}
P\left(m_{i} \mid x^{n x}\right)=\delta\left(m_{i}, x_{i}\right) \tag{12.4}
\end{equation*}
$$

2. Replace all connectors of the dcircuit by arrows pointing in the direction of the bit flow.

Options A and B don't work for digital circuits with feedback loops such as flip-flops. Those could probably be modeled with dynamical bnets.

## Chapter 13

## Do-Calculus

The do-calculus and associated ideas were invented by Judea Pearl and collaborators. This chapter is based on Judea Pearl's books. (See Navigating the ocean of Judea Pearl's Books).

When doing do-calculus, it is convenient to separate the nodes of a bnet into 2 types: visible (observed), and non-visible (not observed, latent, hidden), depending on whether data describing the state of that node is available (visible) or not (non-visible). In this chapter, hidden nodes will be indicated in a bnet diagram by either: (1) enclosing their random variable in a box (as if it were inside a black box) or (2) making the arrows coming out of them dashed. Accordingly, the 3 diagrams in Fig 13.1 all mean the same thing.

A confounder node $\underline{c}$ for nodes $\underline{x}$ and $\underline{y}$ is a root node with arrows pointing from it to both $\underline{x}$ and $\underline{y}$. Thus, $\underline{c}$ acts as a common cause of $\underline{x}$ and $\underline{y}$. The node $\underline{c}$ in Fig 13.1) is an unobserved confounder node.

In this book, we will refer to a path all of whose nodes are observed as an opath.

Figure 13.1: These 3 diagrams are equivalent. They mean that node $\underline{c}$ is hidden. Node $\underline{c}$ is implicit in the middle diagram.

Define an operator $\rho_{\underline{x}}$ that acts on a node $\underline{x}$ of a bnet to delete all the arrows entering $\underline{x}$, thus coverting $\underline{x}$ into a new node $\rho \underline{x}$ that is a root node. Define an analogous operator $\lambda \underline{x}$ that acts on a node $\underline{x}$ of a bnet to delete all the arrows leaving $\underline{x}$, thus converting $\underline{x}$ into a new node $\lambda \underline{x}$ that is a leaf node. $\rho_{\underline{x}}$ and $\lambda_{\underline{x}}$ are depicted in Fig. 13.2.

Figure 13.2: The operator $\rho_{\underline{x}}$ converts node $\underline{x}$ into a root node $\rho \underline{x}$. The operator $\lambda_{\underline{x}}$ converts node $\underline{x}$ into a leaf node $\lambda \underline{x}$.

If you don't know yet what we mean by a a multi-node $\underline{a}$., see Chapter Definition of a Bayesian Network

Given a bnet $G$, we define as follows the operators $\rho_{\underline{a}}$. and $\lambda_{\underline{a}}$. for a multi-node $\underline{a}$..

$$
\begin{equation*}
\rho_{\underline{a} .} G=\left[\prod_{j} \rho_{\underline{a}_{j}}\right] G, \quad \lambda_{\underline{a} \cdot} G=\left[\prod_{j} \lambda_{\underline{a}_{j}}\right] G . \tag{13.1}
\end{equation*}
$$

Consider a bnet whose totality of nodes is labeled $\underline{X}$.. Recall that

$$
\begin{equation*}
P(X .)=\prod_{j} P\left(X_{j} \mid\left(X_{k}\right)_{k: \underline{X}_{k} \in p a\left(\underline{X}_{j}\right)}\right) . \tag{13.2}
\end{equation*}
$$

Define an operator $\rho$ that acts as follows ${ }^{1}$ Let $X .-a .=\left(X_{k}\right)_{k: X_{k} \notin \underline{a}}$.

$$
\begin{align*}
P(X .-a . \mid \rho \underline{a} .=a .) & =\mathcal{N}(!(X .-a .)) \frac{P(X .)}{\prod_{j: \underline{X}_{j} \in \underline{a} .} P\left(X_{j} \mid\left(X_{k}\right)_{k: \underline{X}_{k} \in p a\left(\underline{X}_{j}\right)}\right)}  \tag{13.3}\\
& =\mathcal{N}(!(X .-a .)) \prod_{j: \underline{X}_{j} \notin \underline{a} .} P\left(X_{j} \mid\left(X_{k}\right)_{k: \underline{X}_{k} \in p a\left(\underline{X}_{j}\right)}\right)  \tag{13.4}\\
& \neq P(X .-a . \mid \underline{a} .=a .) . \tag{13.5}
\end{align*}
$$

Also,

$$
\begin{equation*}
P\left(X .-a ., \rho \underline{a} .=a .^{\prime}\right)=P(X .-a . \mid \rho \underline{a} .=a .) \delta\left(a^{\prime} ., a .\right) . \tag{13.6}
\end{equation*}
$$

In words, we replace the TPM for multinode $\underline{a}$. by a deterministic prior distribution.
For instance, for the bnet

$$
\begin{equation*}
\underline{x} \longrightarrow \underline{y} \tag{13.7}
\end{equation*}
$$

with

$$
\begin{equation*}
P(x, y)=P(y \mid x) P(x), \tag{13.8}
\end{equation*}
$$

[^8]one has
\[

$$
\begin{equation*}
P(y \mid \rho \underline{x}=x)=P(y \mid x) \tag{13.9}
\end{equation*}
$$

\]

and

$$
\begin{equation*}
P(x \mid \rho \underline{y}=y)=P(x) . \tag{13.10}
\end{equation*}
$$

This means that $\underline{x}$ causes $\underline{y}$ and $\underline{y}$ does not cause $\underline{x}$.
For the bnet

with

$$
\begin{equation*}
P(x, y, c)=P(y \mid x, c) P(x \mid c) P(c), \tag{13.12}
\end{equation*}
$$

one has

$$
\begin{equation*}
P(y, c \mid \rho \underline{x}=x)=P(y \mid x, c) P(c) . \tag{13.13}
\end{equation*}
$$

Hence,

$$
\begin{equation*}
P(y \mid \rho \underline{x}=x)=\sum_{c} P(y \mid x, c) P(c) . \tag{13.14}
\end{equation*}
$$

This is called adjusting the parents of $\underline{x}$.
For $\underline{b} . \subset \underline{X} .-\underline{a}$. , define

$$
\begin{equation*}
P(b . \mid \rho \underline{a} .=a .)=\sum_{X .-a .-b .} P(X .-a . \mid \rho \underline{a} .=a .), \tag{13.15}
\end{equation*}
$$

and for $\underline{s} . \subset \underline{X} .-\underline{a} .-\underline{b}$. , define

$$
\begin{equation*}
P(b . \mid \rho \underline{a} .=a ., s .)=\frac{P(b ., s . \mid \rho \underline{a} .=a .)}{P(s . \mid \rho \underline{a} .=a .)} . \tag{13.16}
\end{equation*}
$$

$P(b . \mid \rho \underline{a} .=a ., s$.$) is usually denoted instead by P(b . \mid d o(\underline{a} .=a), s.$.$) . I prefer$ to use $\rho$ instead of $d o()$ to remind me that it generates root nodes. I'll still call $\rho$ a do operator.

In $P(y \mid \rho \underline{x}=x)$, node $\underline{x}$ is turned into a root node. This guarantees that there is no confounding node connecting $\underline{x}$ and $\underline{y}$. Such confounding nodes are unwelcomed when calculating causal effects between the 2 variables $\underline{x}$ and $\underline{y}$ because they introduce non-causal correlations between the two. This is also what happens in a Randomized Clinical Trial (RCT). In a RCT with treatment $\underline{x}$, the value of $\underline{x}$ for each patient
is determined by a coin toss, effectively turning $\underline{x}$ into a root node. Hence, the do operator mimics a RCT.
$P(b . \mid \rho \underline{a} .=a ., s$.$) is said to be identifiable (i.e., calculable) if it can be ex-$ pressed in terms of probability distributions that only depend on observed variables and that have no do operators in them. For example, $P(y \mid \rho \underline{x}=x)$ is identifiable for the bnet

but it is non-identifiable for the bnet

For $\underline{x}, \underline{y} \in\{0,1\}$, the average controlled effect (ACE) is defined as

$$
\begin{equation*}
A C E=P(y=1 \mid \rho \underline{x}=1)-P(y=1 \mid \rho \underline{x}=0) \tag{13.19}
\end{equation*}
$$

and the Risk Difference (RD) as

$$
\begin{equation*}
R D=P(y=1 \mid \underline{x}=1)-P(y=1 \mid \underline{x}=0) . \tag{13.20}
\end{equation*}
$$

### 13.1 Parent Adjustment

Suppose that $\underline{x} ., \underline{y} ., \underline{z}$. are disjoint multinodes and their union equals the totality of all nodes of a bnet. Suppose we have data available that allows us to estimate $P(x ., y ., z$.$) .$ Hence, all nodes of the bnet are observable. Furthermore, suppose $\underline{z} .=p a(\underline{x}$.$) . In$ other words, we are considering the bnet

Then

$$
\begin{equation*}
P(y ., z . \mid \rho \underline{x} .=x .)=P(y . \mid x ., z .) P(z .) \tag{13.22}
\end{equation*}
$$

$$
\begin{equation*}
P(y . \mid \rho \underline{x} .=x .)=\sum_{z .} P(y . \mid x ., z .) P(z .) . \tag{13.23}
\end{equation*}
$$

This is called adjusting the parents of $\underline{x}$.
We say that we are adjusting or controlling a variable $\underline{a}$ if we condition a probability on $\underline{a}$ and then we average that probability over $\underline{a}$. More generally, we can adjust a whole multinode $\underline{a}$. together.

Later on, we will introduce a generalization of this parent adjustment called the backdoor adjustment. In a backdoor adjustment, the adjusted multinode is not necessarily the parents of $\underline{x}$. , and $P(x ., y ., z$.$) need not represent the whole bnet.$

### 13.2 3 Rules of do-calculus

Throughout this section, suppose $\underline{a} ., \underline{b} ., \underline{r} ., \underline{s}$. are disjoint multinodes in a bnet $G$.
Recall from Chapter 14 on d-separation, that $\left(\underline{b} . \perp_{G} \underline{a} . \mid \underline{\mid}\right.$., $\underline{s}$.) means that we have established from the d-separation rules that that all paths in $G$ from $\underline{a}$. to $\underline{b}$. are blocked if we condition on $\underline{r} . \cup \underline{s} .$. Recall also that:

- Rule 0: Insertion or deletion of observations, without do operators. ( $\underline{a} .=a . \leftrightarrow$ 1 )
If $\left(\underline{b} . \perp_{G} \underline{a} . \mid \underline{\mid r} ., \underline{s}.\right)$, then $P(b . \mid a ., r ., s)=.P(b . \mid r ., s$.
The 3 rules of do-calculus can be presented in the same format.
- Rule 1: Insertion or deletion of observations ( $\underline{a}=a . \leftrightarrow 1$ )

If $(\underline{b} . \perp \underline{a} . \mid \underline{r} ., \underline{s}$.$) in \rho_{\underline{r}} . G$, then $P(b . \mid a$., $\rho \underline{r} .=r ., s)=.P(b . \mid \rho \underline{r} .=r ., s$.$) .$

- Rule 2: Action or observation exchange ( $\rho \underline{a} .=a . \leftrightarrow \underline{a} .=a$.)

If $(\underline{b} . \perp \underline{a} . \mid \underline{r} ., \underline{s}$.$) in \lambda_{\underline{a} .} . \rho_{\underline{r} .} G$, then $P\left(b . \mid \rho \underline{a} .=a ., \rho \underline{r} .=r_{.}, s.\right)=P(b . \mid a ., \rho \underline{r} .=$ r., s.).

- Rule 3: Insertion and deletion of actions ( $\rho \underline{a} .=a . \leftrightarrow 1$ )

If $(\underline{b} . \perp \underline{a} . \mid \underline{r} ., \underline{s}$.$\left.) in \rho_{\underline{a} .-a n(\underline{s} .}\right) \rho_{\underline{r} .} G$, then $P(b . \mid \rho \underline{a} .=a ., \rho \underline{r} .=r ., s)=.P(b . \mid \rho \underline{r} .=$ r., s.).

These rules have been proven to be sufficient for removing all do operators from an expression for which it is possible to do so.

Next we discuss two theorems that can be proven using do-calculus: the backdoor and the front-door adjustment theorems.

The backdoor theorem adjusts one multinode and the front-door theorem adjusts two.

### 13.3 Backdoor Adjustment

See Chapter 2 for examples of the use of the backdoor adjustment theorem. In this section, we shall mainly be concerned with proving this theorem using do-calculus.

For any two disjoint multinodes $\underline{x}$. and $\underline{y}$., we define a backdoor path from $\underline{x}$. to $\underline{y}$. as a path from $\underline{x}$. and $\underline{y}$. that starts with an arrow pointing into $\underline{x}$.,

Suppose that we have access to data that allows us to estimate a probability distribution $P(x ., y ., z$.$) . Hence, the variables \underline{x} ., y ., \underline{z}$. are ALL the observed (i.e, not hidden). Then we say that the backdoor $\underline{z}$. satisfies the backdoor adjustment criterion relative to $(\underline{x} ., \underline{y}$.$) if$

1. All backdoor paths from $\underline{x}$. to $\underline{y}$. are blocked by $\underline{z}$..
2. $\underline{z} . \cap d e(\underline{x})=.\emptyset$.

Motivation for BD criterion: Part 1 rules out paths from $\underline{x}$ to $\underline{y}$ containing a fork node (confounder) which, if not blocked by $\underline{z}$., would introduce $\overline{\text { a }}$ non-causal correlation (confounder bias). Part 2 rules out a directed path from $\underline{x}$ to $\underline{y}$ that has a mediator node blocked by $\underline{z}$. or a collider node unblocked by $\underline{z}$..

Claim 9 Backdoor Adjustment Theorem
If $\underline{z}$. satisfies the backdoor criterion relative to ( $\underline{x} ., \underline{y}$.$) , then$

$$
\begin{align*}
& P(y . \mid \rho \underline{x} .=x .)= \sum_{z .} P(y . \mid x ., z .) P(z .)  \tag{13.24}\\
&= \underline{z} \cdot=z .  \tag{13.25}\\
& \sum_{z .} \\
& \underline{x} \cdot=x . \longrightarrow \underline{y} .
\end{align*}
$$

## proof:

For simplicity, let us omit the dots from the multinodes. If $z$ satisfies the backdoor criterion relative to $(\underline{x}, \underline{y})$, then $\underline{x}, \underline{y}, \underline{z}$ must have the following structure.

$$
\begin{align*}
& P(y \mid \rho \underline{x}=x)= \\
&= \sum_{m} P(y \mid \rho \underline{x}=x, z) P(z \mid \rho \underline{x}=x) \\
& \text { by Probability Axioms } \\
&= \sum_{P}(y \mid x, z) P(z \mid \rho \underline{x}=x) \\
& P(y \mid \rho \underline{x}=x, z) \rightarrow P(y \mid x, z) \\
& \text { by Rule 2: If }(\underline{b} . \perp \underline{a} \cdot \mid \underline{r} ., \underline{s} .) \text { in } \lambda_{\underline{a}} . \rho_{\underline{r}} . G \text {, then } P(b . \mid \rho \underline{a} .=a ., \rho \underline{r} .=r ., s .)=P(b . \mid a ., \rho \underline{r} .=r ., s .) . \\
& \underline{y} \perp \underline{x} \mid \underline{z} \text { in } \lambda_{\underline{x}} G \\
& \underline{z} \\
&= \sum_{z} P(y \mid x, z) P(z) \\
& P(z \mid \rho \underline{x}=x) \rightarrow P(z) \\
&\text { by Rule 3: If } \left.(\underline{b} . \perp \underline{a} . \mid \underline{r} ., \underline{s} .) \text { in } \rho_{\underline{a} .-a n(\underline{s} .}\right) \rho_{\underline{r}} . G, \text { then } P(b . \mid \rho \underline{a} .=a ., \rho \underline{r} .=r ., s .)=P(b . \mid \rho \underline{r} .=r ., s .) .  \tag{13.27}\\
& \underline{z} \perp \underline{x} \text { in } \rho_{\underline{x}} G \quad \underline{z} \\
& \underline{x} \longrightarrow \underline{y}
\end{align*}
$$

QED
Note that the backdoor adjustment formula can be written as

$$
\begin{align*}
P(y . \mid \rho \underline{x} .=x .) & =\sum_{z .} P(y . \mid x ., z .) P(z .)  \tag{13.28}\\
& =\sum_{z .} \frac{P(y ., x ., z .)}{P(x . \mid z .)} \tag{13.29}
\end{align*}
$$

This assumes $P(x . \mid z) \neq$.0 for all $x ., z$. . This assumption is referred to as positivity, and is violated if $P(x . \mid z)=.\delta(x ., x .(z).) . P(x . \mid z$.$) is called the propensity score of x$. given $z$.. This equation does inverse probability weighting. One can approximate $P(x . \mid z$. $)$ in this equation to get an approximation to $P(y \mid \rho \underline{x}=x)$.

### 13.4 Front Door Adjustment

See Chapter 17 for examples of the use of the front-door adjustment theorem. In this section, we shall mainly be concerned with proving this theorem using do-calculus.

Suppose that we have access to data that allows us to estimate a probability distribution $P(x ., m ., y$.$) . Hence, the variables \underline{x} ., \underline{m}$., $\underline{y}$. are ALL the observed (i.e, not hidden). Then we say that the front-door $\underline{m}$. satisfies the front-door adjustment criterion relative to ( $\underline{x} ., \underline{y}$.) if

1. All directed paths from $\underline{x}$. to $\underline{y}$. are intercepted by (i.e., have a node in) $\underline{m}$..
2. All backdoor paths from $\underline{x}$. to $\underline{m}$. are blocked (by $\emptyset$ ).
3. All backdoor paths from on $\underline{m}$. to $\underline{y}$. are blocked by $\underline{x}$..

Claim 10 Front-Door Adjustment Theorem
If $\underline{m}$. satisfies the front-door criterion relative to $(\underline{x} ., \underline{y}$.$) , and P(x ., m)>$.0 , then

$$
\begin{array}{r}
P(y . \mid \rho \underline{x} .=x .)=\sum_{m \cdot} \underbrace{\left[\sum_{x \cdot \prime^{\prime}} P\left(y . \mid x^{\prime} \cdot, m .\right) P\left(x^{\prime} .\right)\right]}_{P(y \cdot \mid \rho \underline{m} \cdot=m .)} \underbrace{P(m \cdot \mid x .)}_{P(m \cdot \mid \rho \underline{x}=x .)} \\
=\underline{x} \cdot=x \cdot{ }^{\prime}  \tag{13.31}\\
\sum_{m \cdot, x . \prime^{\prime}} \\
\underline{x} \cdot=x . \longrightarrow \underline{m} \cdot=m \cdot \longrightarrow \underline{y} .
\end{array}
$$

proof: (See also Ref. [22] for a proof of the Front-Door Adjustment Theorem without using do-calculus.)

For simplicity, let us omit the dots from the multinodes. If $\underline{m}$ satisfies the front-door criterion relative to $(\underline{x}, \underline{y})$, then $\underline{x}, \underline{m}, \underline{y}$ must have the following structure, where node $\underline{c}$ is hidden.

Continues in next page.

$$
\text { by Rule 2: If }(\underline{b} . \perp \underline{a} \cdot \mid \underline{r} ., \underline{s} .) \text { in } \lambda_{\underline{a} .} \rho_{\underline{r} .} G \text {, then } P(b . \mid \rho \underline{a} .=a ., \rho \underline{r} .=r ., s .)=P(b . \mid a ., \rho \underline{r} .=r ., s .) \text {. }

\end{aligned}
\end{aligned}
$$

QED

## Chapter 14

## D-Separation

Before reading this chapter, I recommend that you read Chapter Definition of a Bayesian Network on the definition of bnets.

A path $\gamma$ that isn't a loop can have 3 types of intermediate nodes $\underline{x}$ (an intermediate node of $\gamma$ is a node in $\gamma$ that isn't one of the two end nodes). Suppose $\underline{a}$ and $\underline{b}$ are the two neighbors of $\underline{x}$. Then the 3 possible cases are:

1. mediator node: $(\underline{a} \leftarrow \underline{x} \leftarrow \underline{b})$ or $(\underline{a} \rightarrow \underline{x} \rightarrow \underline{b})$
2. fork node: $(\underline{a} \leftarrow \underline{x} \rightarrow \underline{b})$
3. collider node: $(\underline{a} \rightarrow \underline{x} \leftarrow \underline{b})$

We say that a non-loop path $\gamma$ from $\underline{a}$ to $\underline{b}$ (i.e., with end nodes $\underline{a}, \underline{b}$ ) is blocked by a multinode $\underline{Z}$. if one or more of the following statements is true:

1. There is a node $\underline{x} \in \underline{Z}$. which is a mediator or a fork of $\gamma$.
2. $\gamma$ contains a collider node $\underline{c}$ and $(\underline{c} \cup d e(\underline{c})) \cap \underline{Z}$. $=\emptyset$ (i.e., neither $\underline{c}$ nor any of the descendants of $\underline{c}$ is contained in $\underline{Z}$.)

This definition of a blocked path is easy to remember if one thinks of the following analogy with pipes carrying a fluid. Think of path $\gamma$ as if it were a pipe carrying a fluid. Think of the nodes of $\gamma$ as junctions in the pipe. If $\underline{Z}$. intersects $\gamma$ at either a mediator or a fork junction, that blocks the pipe flow. A collider junction $\underline{c}$ is like a blackhole or a huge leak. Its presence blocks passage of the fluid as long as neither $\underline{c}$ nor any of the descendants of $\underline{c}$ are in $\underline{Z}$. If, on the other hand, $\underline{c} \in \underline{Z}$., or $\underline{c}^{\prime} \in \underline{Z}$. where $\underline{c}^{\prime} \in d e(\underline{c})$, then that acts as a complete (in the case of $\underline{c} \in \underline{Z}$.) or a partial (in the case of $\underline{c}^{\prime} \in \underline{Z}$.) bridge across the blackhole.

See Fig. 14.1 for some examples of paths that are blocked or not blocked by a multinode $\underline{Z}$..

Figure 14.1: Examples of paths that are blocked or not blocked by a multinode $\underline{Z}$.. Nodes belonging to $\underline{Z}$. are colored red.

Given 3 disjoint multinodes $\underline{A}$., $\underline{B}$., $\underline{Z}$. of a graph $G$, we write " $\underline{A} . \perp_{G} \underline{B} \cdot \mid \underline{Z}$." or say " $\underline{A}$. and $\underline{B}$. are d-separated by $\underline{Z}$. in $G$ " iff there exists no path $\gamma$ from $\underline{a} \in \underline{A}$., to $\underline{b} \in \underline{B}$. which is not blocked by $\underline{Z} . \boldsymbol{I}^{1}$

The minimal Markov blanket (see Chapter 28) of a node $\underline{a}$ is the smallest multinode $\underline{Z}$. such that $\underline{a} \perp_{G} \underline{b} \underline{Z}$. for all $\underline{b} \notin \underline{a} \cup \underline{Z}$..

We are finally ready to state the d-separation theorem, without proof.
A probability distribution $P$ is compatible with a DAG $G$ if $P$ and $G$ have the same random variables, and they can be combined to form a bnet without contradictions; i.e., one can calculate all the TPMs from $P$ and multiply them together to obtain $P$ again.

## Claim 11 (d-separation Theorem)

Suppose $\underline{A}$., $\underline{B} ., \underline{Z}$. are disjoint multinodes of a $D A G G$.
If $\underline{A} . \perp_{G} \underline{B} \cdot \mid \underline{Z}$., then $P(B . \mid A ., Z)=.P(B . \mid Z$.$) for all B ., A ., Z$., for all $P$ compatible with $G$.

The full converse of the theorem can also be proven, but we won't be using it in this book.

Often, the right hand side of this theorem is stated as " $\underline{A}$. $\perp_{P} \underline{B} . \mid \underline{Z}$. for all

Note that the following are equivalent:

- $P(B . \mid A ., Z)=.P(B . \mid Z$.$) for all B., A., Z..$
- $\underline{A} . \perp_{P} \underline{B} \cdot \mid \underline{Z}$.

[^9]- $H(\underline{A} .: \underline{B} \cdot \mid \underline{Z})=$.0 (see Chapter Notational Conventions and Preliminaries for definition of conditional mutual information (CMI))

## Extra stuff: mostly only for pure mathematicians

Below, we will use the notation $n d e(\underline{a})$ to denote all nondescendants, including $\underline{a}$ itself, of a node $\underline{a}$ in a DAG $G$; i.e., all nodes of $G$ that are not in $d e(\underline{a}) \cup \underline{a}$, where $d e(\underline{a})$ is defined in Chapter Definition of a Bayesian Network.

Given a DAG $G$, define the following sets of d-separations $2^{2}$
$D S(G)=\left\{\left(\underline{A} . \perp_{G} \underline{B} . \mid \underline{Z}.\right): \underline{A}, \underline{B} \cdot, \underline{Z}\right.$. are multinodes of $\left.G\right\}$.
$D S_{\text {min }}(G)=\left\{\left(\underline{A} . \perp_{G} n d e(\underline{A}) \mid. p a(\underline{A}).\right): \underline{A}\right.$. is a multinode of $\left.G\right\}$.
See Chapter 38 for an example where set $D S_{\min }(G)$ is calculated for a particular DAG $G$.

Claim 12 For all DAGs $G, D S(G)=D S_{\min }(G)$.
Given a probability distribution $P$, define the following set of conditional independencies:

$$
\begin{equation*}
C I(P)=\left\{\left(\underline{A} \cdot \perp_{P} \underline{B} \cdot \mid \underline{Z} \cdot\right): \underline{A} \cdot, \underline{B} \cdot, \underline{Z} . \text { are multinodes of } P\right\}, \tag{14.10}
\end{equation*}
$$

For a DAG $G$ and a probability distribution $P$ compatible with $G$, define a map $\phi$ by

$$
\begin{align*}
\phi: D S_{\min }(G) & \rightarrow C I(P)  \tag{14.11}\\
\phi: \underline{A} . \perp_{G} n d e(\underline{A} .) \mid p a(\underline{A} .) & \mapsto \underline{A} \cdot \perp_{P} n d e(\underline{A} .) \mid p a(\underline{A} .) \tag{14.12}
\end{align*}
$$

In general, this map is 1-1 but not onto.
Claim 13 For a bnet with a DAG $G$ and a total probability distribution $P$, the map $\phi$ is a bijection.
$D S(G)$ does not fully specify a DAG. DAGs with the same $D S(G)$ are said to be d-separation equivalent. See Chapter 38 for more info about d-separation equivalence.

[^10]
## Chapter 15

## Dynamic Bayesian Networks

Figure 15.1: Example of a dynamic bnet. The pattern of red arrows is repeated $T-1$ times.

A dynamic bnet is simply a time homogeneous Markov chain (see Chapter 30) for which each node is called a time slice, and each time slice represents at finer resolution a sub-DAG which is the same between any 2 successive time slices. Fig. 15.1 gives an example of a dynamic bnet. In Fig 15.1, we've drawn the 3 nodes of each time slice vertically, and labeled them with a superscript . ${ }^{(t)}$, where $t \in\{0,1 \ldots, T-1\}$ is the time of the slice. To fully specify the dynamic bnet of Fig. 15.1, we would also have to specify the TPMs

$$
\begin{aligned}
& P\left(c^{(0)}\right), \\
& P\left(b^{(0)}\right) \\
& P\left(c^{(1)} \mid c^{(0)}\right), \\
& P\left(b^{(1)} \mid b^{(0)}, a^{(1)}\right) \\
& P\left(a^{(1)} \mid b^{(0)}\right) .
\end{aligned}
$$

Dynamic bnets are very common in AI and Data Science. Kalman filters (Chapter 25), Hidden Markov Models (Chapter 20) and Recurrent Neural Networks (Chapter 41) are famous examples of dynamic bnets.

Bnets are acyclic; they can't have cycles (i.e, closed directed paths). Yet feedback loops are an important concept in Science. So what is the equivalent of feedback loops in the bnet world? Dynamic bnets are. Fig. 15.2 represents Fig. 15.1
more compactly using feedback loops. Any bnet with feedback loops can be "unrolled" into a dynamic bnet.

Figure 15.2: Dynamic bnet of Fig 15.1 represented more compactly using feedback loops. Arrows labelled + point from nodes of the $t$ time slice to nodes of the $t+1$ time slice.

## Chapter 16

## Expectation Maximization

This chapter is based on Refs. 52] and [84.
The Expectation Maximization (EM) algorithm is commonly used in Data Science to find the maximum over an unknown parameter $\theta$ of a likelihood function

$$
\begin{equation*}
P(\vec{x} \mid \theta)=\sum_{\vec{h}} P(\vec{x}, \vec{h} \mid \theta) \tag{16.1}
\end{equation*}
$$

where $\vec{x}$ denotes the observed variables, and $\vec{h}$ denotes the latent variables. Both $\theta$ and $\vec{h}$ are hidden (i.e., unobserved) ${ }^{1}$

Figure 16.1: bnet for EM with $n s a m=3$.
The bnet for the EM algorithm is given by Fig 16.1 for $n s a m=3$. Later on in this chapter, we will give the node TPMs for this bnet for the special case in which $P(x[\sigma] \mid \theta)$ is a mixture (i.e., weighted sum) of Gaussians.

[^11]Note that if we erase the $\underline{h}[\sigma]$ nodes from Fig 16.1, we get the bnet for naive Bayes, which is used for classification into the states of $\underline{\theta}$. However, there is one big difference. With naive Bayes, the leaf nodes have different TPMs. Here, we will assume they are i.i.d. Naive Bayes is used for classification: i.e., given the states of the leaf nodes, we infer the state of the root node. EM is used for clustering; i.e., given many i.i.d. samples, we fit their distribution by a weighted sum of prob distributions, usually Gaussians.

Let
$\mathcal{L}=$ likelihood function.
nsam $=$ number of samples.
$\vec{x}=(x[0], x[1], \ldots, x[n s a m-1]) x[\sigma] \in S_{\underline{x}}$ for all $\sigma$.
$\vec{h}=(h[0], h[1], \ldots, h[n s a m-1]) h[\sigma] \in S_{\underline{h}}$ for all $\sigma$.
We assume that the samples $(x[\sigma], h[\sigma])$ are i.i.d. for different $\sigma$ at fixed $\theta$. What this means is that there are probability distributions $P_{\underline{x} \mid \underline{h}, \underline{\theta}}$ and $P_{\underline{\underline{h} \mid \underline{\theta}}}$ such that

$$
\begin{equation*}
P(\vec{x}, \vec{h} \mid \theta)=\prod_{\sigma}\left[P_{\underline{x} \mid \underline{h}, \underline{\theta}}(x[\sigma] \mid h[\sigma], \theta) P_{\underline{h} \mid \underline{\theta}}(h[\sigma] \mid \theta)\right] . \tag{16.2}
\end{equation*}
$$

Definition of likelihood functions:

$$
\begin{equation*}
\underbrace{P(\vec{x} \mid \theta)}_{\mathcal{L}(\theta ; \vec{x})}=\sum_{\vec{h}} \underbrace{P(\vec{x}, \vec{h} \mid \theta)}_{\mathcal{L}(\theta ; \vec{x}, \vec{h})} \tag{16.3}
\end{equation*}
$$

$\theta^{*}=$ maximum likelihood estimate of $\theta$ (no prior $P(\theta)$ assumed):

$$
\begin{equation*}
\theta^{*}=\underset{\theta}{\operatorname{argmax}} \mathcal{L}(\theta ; \vec{x}) \tag{16.4}
\end{equation*}
$$

### 16.1 The EM algorithm:

## 1. Expectation step $\left\{^{2}\right.$

$$
\begin{equation*}
Q\left(\theta \mid \theta^{(t)}\right)=E_{\vec{h} \mid \vec{x}, \theta^{(t)}} \ln P(\vec{x}, \vec{h} \mid \theta) \tag{16.5}
\end{equation*}
$$

2. Maximization step:

$$
\begin{equation*}
\theta^{(t+1)}=\underset{\theta}{\operatorname{argmax}} Q\left(\theta \mid \theta^{(t)}\right) . \tag{16.6}
\end{equation*}
$$

Claim: $\lim _{t \rightarrow \infty} \theta^{(t)}=\theta^{*}$.

[^12]

Figure 16.2: The EM algo generates a sequence of parameter estimates $\left(\theta^{(t)}\right)_{t=0,1,2, \ldots}$ that converges to the optimum (i.e., best-fit) parameter $\theta^{*}$.

Fig 16.2 portrays the recursive nature of the EM algo as a dynamical, recurrent bnet. For Fig. 16.2, the TPMs, printed in blue, for the $\underline{\theta}^{(t)}$ nodes for $t=1,2, \ldots$, are as follows:

$$
\begin{equation*}
P\left(\theta^{(t+1)} \mid \vec{x}, \theta^{(t)}\right)=\delta\left(\theta^{(t+1)}, \underset{\theta}{\operatorname{argmax}} Q\left(\theta \mid \theta^{(t)}\right)\right) . \tag{16.7}
\end{equation*}
$$

### 16.1.1 Motivation

$$
\begin{align*}
Q\left(\theta \mid \theta^{(t)}\right) & =E_{\vec{h} \mid \vec{x}, \theta^{(t)}} \ln P(\vec{x}, \vec{h} \mid \theta)  \tag{16.8}\\
& =E_{\vec{h} \mid \vec{x}, \theta^{(t)}}[\ln P(\vec{h} \mid \vec{x}, \theta)+\ln P(\vec{x} \mid \theta)]  \tag{16.9}\\
& =-D_{K L}\left(P\left(\vec{h} \mid \vec{x}, \theta^{(t)}\right) \| P(\vec{h} \mid \vec{x}, \theta)\right)-H\left[P\left(\underline{\vec{h}} \mid \vec{x}, \theta^{(t)}\right)\right]+\ln P(\vec{x} \mid \theta) \tag{16.10}
\end{align*}
$$

When $\theta^{(t)}=\theta$, this becomes

$$
\begin{equation*}
Q(\theta \mid \theta)=-H[P(\underline{\vec{h}} \mid \vec{x}, \theta)]+\ln P(\vec{x} \mid \theta) . \tag{16.11}
\end{equation*}
$$

Hence,

$$
\begin{align*}
\partial_{\theta} Q(\theta \mid \theta) & =-\sum_{\vec{h}} \partial_{\theta} P(\underline{\vec{h}} \mid \vec{x}, \theta)+\partial_{\theta} \ln P(\vec{x} \mid \theta)  \tag{16.12}\\
& =\partial_{\theta} \ln P(\vec{x} \mid \theta) \tag{16.13}
\end{align*}
$$

So if $\theta^{(t)} \rightarrow \theta$ and $Q(\theta \mid \theta)$ is max at $\theta=\theta^{*}$, then $\ln P(\vec{x} \mid \theta)$ is max at $\theta=\theta^{*}$ too.

For a more rigorous proof that $\lim _{t \rightarrow \infty} \theta^{(t)}=\theta^{*}$, see Wikipedia article Ref. 52 and references therein.

Figure 16.3: Function $\mu\left(\theta \mid \theta^{(t)}\right)$ minorizes the function $\mathcal{L}(\theta)$. Note that $\mu\left(\theta \mid \theta^{(t)}\right)$ is always below $\mathcal{L}(\theta)$. "max" indicates $\theta^{(t+1)}=\underset{\theta}{\operatorname{argmax}} \mu\left(\theta \mid \theta^{(t)}\right)$. "kiss" indicates $\mu\left(\theta^{(t)} \mid \theta^{(t)}\right)=\mathcal{L}\left(\theta^{(t)}\right)$.

### 16.2 Minorize-Maximize (MM) algorithms

A function $\mu\left(\theta \mid \theta^{(t)}\right)$ is said to minorize a target function $\mathcal{L}(\theta)$ iff for all $\theta$ at fixed $\theta^{(t)}$, it satisfies the " $\mu \leq \mathcal{L}$ property"

$$
\begin{equation*}
\mu\left(\theta \mid \theta^{(t)}\right) \leq \mathcal{L}(\theta), \tag{16.14}
\end{equation*}
$$

and the " $\mu=\mathcal{L}$ property"

$$
\begin{equation*}
\mu\left(\theta^{(t)} \mid \theta^{(t)}\right)=\mathcal{L}\left(\theta^{(t)}\right) \tag{16.15}
\end{equation*}
$$

We recursively maximize a minorizing function $\mu\left(\theta \mid \theta^{(t)}\right)$ if we define a sequence $\left(\theta^{(t)}\right)_{t=0,1, \ldots}$ as follows:

$$
\begin{equation*}
\theta^{(t+1)}=\underset{\theta}{\operatorname{argmax}} \mu\left(\theta \mid \theta^{(t)}\right) . \tag{16.16}
\end{equation*}
$$

The sequence $\left(\mathcal{L}\left(\theta^{(t)}\right)\right)_{t=0,1,2, \ldots}$ generated by recursively maximizing a minorizing function must be nondecreasing:

$$
\begin{equation*}
\mathcal{L}\left(\theta^{(t+1)}\right) \geq \mu\left(\theta^{(t+1)} \mid \theta^{(t)}\right) \geq \mu\left(\theta^{(t)} \mid \theta^{(t)}\right)=\mathcal{L}\left(\theta^{(t)}\right) \tag{16.17}
\end{equation*}
$$

A minorize-maximize (MM) algorithm is any algo that specifies a minorizing function $\mu\left(\theta \mid \theta^{(t)}\right)$ for a particular target function $\mathcal{L}(\theta)$. One can also define a
majorize-minimize algo (also called MM) by inverting the inequalities throughout.

The EM algo is an MM algo. Indeed, if we define

$$
\begin{equation*}
\mathcal{L}(\theta)=\ln P(\vec{x} \mid \theta) \tag{16.18}
\end{equation*}
$$

and

$$
\begin{equation*}
\mu\left(\theta \mid \theta^{(t)}\right)=Q\left(\theta \mid \theta^{(t)}\right)+H\left(P\left(\underline{h} \mid \vec{x}, \theta^{(t)}\right)\right. \tag{16.19}
\end{equation*}
$$

then Eq. 16.10 establishes the $\mu \leq \mathcal{L}$ and $\mu=\mathcal{L}$ properties required of a minorizing function.

How an MM algo works is portrayed in Fig. 16.3 .

### 16.3 Examples

### 16.3.1 Gaussian mixture

$x[\sigma] \in \mathbb{R}^{d}=S_{\underline{x}}$. $S_{\underline{\underline{h}}}$ discrete and not too large. $n_{\underline{h}}=\left|S_{\underline{h}}\right|$ is number of Gaussians that we are going to fit the samples with.

Let

$$
\begin{equation*}
\theta=\left[w_{h}, \mu_{h}, \Sigma_{h}\right]_{h \in S_{\underline{\underline{h}}}}, \tag{16.20}
\end{equation*}
$$

where $\left[w_{h}\right]_{h \in S_{h}}$ is a probability distribution of weights, and where $\mu_{h} \in \mathbb{R}^{d}$ and $\Sigma_{h} \in$ $\mathbb{R}^{d \times d}$ are the mean value vector and covariance matrix of a $d$-dimensional Gaussian distribution.

The TPMs, printed in blue, for the nodes of Fig, 16.1, for the special case of a mixture of Gaussians, are as follows:

$$
\begin{gather*}
P(x[\sigma]|h[\sigma]| \theta)=\mathcal{N}_{d}\left(x[\sigma] ; \mu_{h[\sigma]}, \Sigma_{h[\sigma]}\right)  \tag{16.21}\\
P(h[\sigma] \mid \theta)=w_{h[\sigma]} \tag{16.22}
\end{gather*}
$$

Note that

$$
\begin{align*}
P(x[\sigma] \mid \theta) & =\sum_{h} P(x[\sigma] \mid h[\sigma]=h, \theta) P(h[\sigma]=h \mid \theta)  \tag{16.23}\\
& =\sum_{h} w_{h} \mathcal{N}_{d}\left(x[\sigma] ; \mu_{h}, \Sigma_{h}\right) \tag{16.24}
\end{align*}
$$

$$
\begin{align*}
P(\vec{x}, \vec{h} \mid \theta) & =\prod_{\sigma}\left[w_{h[\sigma]} \mathcal{N}_{d}\left(x[\sigma] ; \mu_{h[\sigma]}, \Sigma_{h[\sigma]}\right)\right]  \tag{16.25}\\
& =\prod_{\sigma} \prod_{h}\left[w_{h} \mathcal{N}_{d}\left(x[\sigma] ; \mu_{h}, \Sigma_{h}\right)\right]^{\mathbb{1}(h=h[\sigma])} \tag{16.26}
\end{align*}
$$

Old Faithful: See Wikipedia Ref. [52] for an animated gif of a classic example of using EM to fit samples with a Gaussian mixture. Unfortunately, could not include it here because pdflatex does not support animated gifs. The gif shows samples in a 2 dimensional space (eruption time, delay time) from the Old Faithful geyser. In that example, $d=2$ and $n_{\underline{\underline{h}}}=2$. Two clusters of points in a plane are fitted by a mixture of 2 Gaussians.

K-means clustering is often presented as the main competitor to EM for doing clustering (non-supervised learning). In K-means clustering, the sample points are split into $K$ mutually disjoint sets $S_{0}, S_{1}, \ldots, S_{K-1}$. The algorithm is easy to describe:

1. Initialize by choosing at random $K$ data points $\left(\mu_{k}\right)_{k=0}^{K-1}$ called means or centroids and placing $\mu_{k}$ in $S_{k}$ for all $k$.
2. STEP 1: For each data point, add it to the $S_{k}$ whose centroid $\mu_{k}$ is closest to it.
3. STEP 2: Recalculate the centroids. Set $\mu_{k}$ equal to the mean value of set $S_{k}$.
4. Repeat steps 1 and 2 until the centroids stop changing by much.

Step 1 is analogous to the expectation step in EM, and Step 2 to the maximization step in EM ( $\theta$ estimation versus $\mu_{k}$ estimation). We won't say anything further about K-means clustering because it isn't related to bnets in any way, and this is a book about bnets. For more info about K-means clustering, see Ref. 61].

### 16.3.2 Blood Genotypes and Phenotypes

Notation: $\underline{\vec{a}}=(\underline{a}[\sigma])_{\sigma=0,1, \ldots, n s a m-1}$, where nsam is the number of samples. Will sometimes denote $a[\sigma]$ by $a^{[\sigma]}$.

Suppose $\underline{\vec{x}}=\left(\underline{\vec{x}}_{0}\right)$ (i.e., just one component)
$\underline{\vec{h}}=\left(\overrightarrow{\underline{h}}_{0}\right)$ (i.e., just one component)
$\underline{h}[\sigma] \in S_{\underline{k}}=\{A A, A O, B B, B O, O O, A B\}$ (the 6 blood genotypes)
$\underline{x}[\sigma] \in S_{\underline{x}}=\{A, B, O, A B\}$ (the 4 blood phenotypes)

Figure 16.4: bnet for blood phenotypes $x[\sigma]$ and genotypes $h[\sigma]$.
For the bnet of Fig. $\sqrt{16.4}$, the TPMs, printed in blue, are:

$$
P\left(h^{[\sigma]} \mid \theta\right)=\begin{array}{c|c} 
& \\
\hline A A & p_{A}^{2} \\
A O & 2 p_{A} p_{O}  \tag{16.27}\\
B B & p_{B}^{2} \\
B O & 2 p_{B} p_{O} \\
O O & p_{O}^{2} \\
A B & 2 p_{A} p_{B}
\end{array},
$$

where $p_{A}+p_{B}+p_{O}=1$.

$$
\left.\begin{array}{rl} 
& \\
P\left(x^{[\sigma]} \mid h^{[\sigma]}, \theta\right)= & A A  \tag{16.29}\\
A & A
\end{array}\right) B B \begin{array}{lllll} 
& 1 & 1 & 0 & 0 \\
0 & 0 & A B \\
B & 0 & 0 & 1 & 1 \\
0 & 0 \\
O & 0 & 0 & 0 & 0 \\
1 & 0 \\
A B & 0 & 0 & 0 & 0 \\
0 & 1 \\
& \theta=\left(p_{A}, p_{B}\right)
\end{array}
$$

Multiplying the TPMs in Eqs. 16.27 and 16.28 , we get

$$
P\left(x^{[\sigma]} \mid \theta\right)=\begin{array}{l|l} 
& \\
\hline A & p_{A}^{2}+2 p_{A} p_{O}\left(=\pi_{A}\right)  \tag{16.30}\\
B & p_{B}^{2}+2 p_{B} p_{O}\left(=\pi_{B}\right) \\
O & p_{O}^{2}\left(=\pi_{O}\right) \\
A B & 2 p_{A} p_{B}\left(=\pi_{A B}\right)
\end{array}
$$

Note that

$$
\begin{align*}
P(\vec{x} \mid \theta) & =\prod_{\sigma} P\left(x^{[\sigma]} \mid \theta\right)  \tag{16.31}\\
& =\left(\pi_{A}\right)^{N_{A}}\left(\pi_{B}\right)^{N_{B}}\left(\pi_{O}\right)^{N_{O}}\left(\pi_{A B}\right)^{N_{A B}} \tag{16.32}
\end{align*}
$$

where $N_{x}$ for $x \in S_{\underline{x}}=\{A, B, O, A B\}$ are the counts from the data. We can get estimates for the parameters $p_{A}$ and $p_{B}$ right here without doing EM. Just note that

$$
\begin{equation*}
\hat{\pi}_{x}=\frac{N_{x}}{N_{+}} \tag{16.33}
\end{equation*}
$$

for $x \in S_{\underline{x}}$, where $N_{+}=\sum_{x} N_{x}$. Eqs. (16.33) give 4 quadratic equations that can be solved for the parameters $p_{A}, p_{B}$ in terms of the observed counts $N_{x}$ for $x \in S_{\underline{x}}$.

If, instead, you want to find the optimum parameters $p_{A}, p_{B}$ using EM, note that

$$
\begin{align*}
Q\left(\theta \mid \theta^{(t)}\right) & =\sum_{\vec{h}} P\left(\vec{h} \mid \theta^{(t)}\right) \ln P(\vec{x}, \vec{h} \mid \theta)  \tag{16.34}\\
& =\sum_{\vec{h}}\left[\prod_{\sigma} P\left(h^{[\sigma]} \mid \theta^{(t)}\right)\right] \ln \left[\prod_{\sigma} P\left(x^{[\sigma]}, h^{[\sigma]} \mid \theta\right)\right]  \tag{16.35}\\
& =\sum_{\sigma} \sum_{h^{[\sigma]}} P\left(h^{[\sigma]} \mid \theta^{(t)}\right) \ln P\left(x^{[\sigma]}, h^{[\sigma]} \mid \theta\right)  \tag{16.36}\\
& =\sum_{\sigma} \sum_{h^{[\sigma]}} P\left(h^{[\sigma]} \mid \theta^{(t)}\right)\left[\ln P\left(x^{[\sigma]} \mid h^{[\sigma]}, \theta\right)+\ln P\left(h^{[\sigma]} \mid \theta\right)\right]  \tag{16.37}\\
& =n s a m \sum_{h^{[\sigma]}} P\left(h^{[\sigma]} \mid \theta^{(t)}\right) \ln P\left(h^{[\sigma]} \mid \theta\right) \tag{16.38}
\end{align*}
$$

### 16.3.3 Missing Data/Imputation

The previous example on blood genotypes and phenotypes assumed no missing data in compiling the counts $N_{x}$. But what if there is missing data? Can one still apply the EM algo in that case? Yes! See Chapter 32.

## Chapter 17

## Front-door Adjustment

The front-door (FD) adjustment theorem is proven in Chapter 13 from the rules of docalculus. The goal of this chapter is to give examples of the use of that theorem. We will restate the theorem in this chapter, sans proof. There is no need to understand the theorem's proof in order to use it. However, you will need to skim Chapter 13 in order to familiarize yourself with the notation used to state the theorem. This chapter also assumes that you are comfortable with the rules for checking for d-separation. Those rules are covered in Chapter 14 .

Suppose that we have access to data that allows us to estimate a probability distribution $P(x ., m ., y$.$) . Hence, the variables \underline{x} ., \underline{m} ., \underline{y}$. are ALL the observed (i.e, not hidden). Then we say that the front-door $\underline{m}$. satisfies the front-door adjustment criterion relative to ( $\underline{x} ., \underline{y}$.) if

1. All directed paths from $\underline{x}$. to $\underline{y}$. are intercepted by (i.e., have a node in) $\underline{m}$..
2. All backdoor paths from $\underline{x}$. to $\underline{m}$. are blocked (by $\emptyset$ ).
3. All backdoor paths from on $\underline{m}$. to $\underline{y}$. are blocked by $\underline{x}$.

## Claim 14 Front-Door Adjustment Theorem

If $\underline{m}$. satisfies the front-door criterion relative to $(\underline{x} ., \underline{y}$.$) , and P(x ., m)>$.0 , then

$$
\begin{align*}
& P(y . \mid \rho \underline{x} .=x .)=\sum_{m .} \underbrace{\left[\sum_{x .{ }^{\prime}} P\left(y . \mid x^{\prime} ., m .\right) P\left(x^{\prime} .\right)\right]}_{P(y . \mid \rho \underline{m} .=m .)} \underbrace{P(m . \mid x .)}_{P(m . \mid \rho \underline{x} .=x .)}  \tag{17.1}\\
& \begin{array}{r}
=\underline{x} \cdot=x \cdot{ }^{\prime} \\
\underline{\sum_{m ., x . \prime}^{\prime}}=x . \longrightarrow \underline{m} .=m . \longrightarrow \underline{y} .
\end{array} \tag{17.2}
\end{align*}
$$

proof: See Chapter 13
QED

### 17.1 Examples

1. 

If $\underline{x} .=\underline{x}, \underline{m} .=\underline{m}$ and $\underline{y} .=\underline{y}$, then the FD criterion is satisfied. Can't satisfy backdoor criterion because $\underline{z}$. must be observed so can't block backdoor path $\underline{x}-\underline{c}-\underline{\underline{y}}$.
2.

If $\underline{x}$. $=\underline{x}, \underline{m} .=\underline{m}$ and $\underline{y} .=\underline{y}$, then the FD criterion is satisfied. Can't satisfy backdoor criterion because to block backdoor path $\underline{x}-\underline{c}-\underline{y}$, need to condition on $\underline{c}$ (i.e., need $\underline{c} \in \underline{z}$.) but if this is true, then long path $\underline{x}-\underline{w}_{1}-\underline{z}_{1}-\underline{c}-\underline{z}_{2}-\underline{w}_{2}-\underline{y}$ becomes unblocked.

## Chapter 18

## Generative Adversarial Networks (GANs)

Figure 18.1: Generative Adversarial Network (GAN)
Original GAN, Ref. [9](2014).
Generator $G$ (counterfeiter) generates samples $\vec{f}$ of fake money and submits them to Discriminator $D$ (Treasury agent). $D$ also gets samples $\vec{r}$ of real money. $D$ submits veredict $V \in[0,1]$. $G$ depends on parameter $\theta_{G}$ and $D$ on parameter $\theta_{D}$. Veredict $V$ and initial $\theta_{G}, \theta_{D}$ are used to get new parameters $\theta_{G}^{\prime}, \theta_{D}^{\prime}$. Process is

Figure 18.2: Discriminator node $\underline{V}$ in Fig 18.1 can be split into 3 nodes $\underline{\vec{c}}, \underline{\vec{d}}$ and $\underline{V}$.
repeated (Dynamical Bayesian Network) until saddle point in $V\left(\theta_{G}, \theta_{D}\right)$ is reached. $D$ makes $G$ better and vice versa. Zero-sum game between $D$ and $G$.

Let $\mathcal{D}$ be the domain of $D\left(\cdot, \theta_{D}\right)$. Assume that for any $x \in \mathcal{D}$,

$$
\begin{equation*}
0 \leq D\left(x, \theta_{D}\right) \leq 1 \tag{18.1}
\end{equation*}
$$

For any $S \subset \mathcal{D}$, define

$$
\begin{equation*}
\sum_{x \in S} D\left(x, \theta_{D}\right)=\lambda\left(S, \theta_{D}\right) \tag{18.2}
\end{equation*}
$$

In general, $G\left(\cdot, \theta_{G}\right)$ need not be real valued.
Assume that for every $u \in S_{\underline{u}}, G\left(u, \theta_{G}\right)=f \in S_{\underline{f}} \subset \mathcal{D}$. Define

$$
\begin{equation*}
\bar{D}\left(f, \theta_{D}\right)=1-D\left(f, \theta_{D}\right) \tag{18.3}
\end{equation*}
$$

Note that

$$
\begin{equation*}
0 \leq \bar{D}\left(f, \theta_{D}\right) \leq 1 \tag{18.4}
\end{equation*}
$$

Define:

$$
\begin{equation*}
V\left(\theta_{G}, \theta_{D}\right)=\sum_{r} P(r) \ln D\left(r, \theta_{D}\right)+\sum_{u} P(u) \ln \bar{D}\left(G\left(u, \theta_{G}\right), \theta_{D}\right) \tag{18.5}
\end{equation*}
$$

We want the first variation of $V\left(\theta_{G}, \theta_{D}\right)$ to vanish.

$$
\begin{equation*}
\delta V\left(\theta_{G}, \theta_{D}\right)=0 . \tag{18.6}
\end{equation*}
$$

This implies

$$
\begin{equation*}
\partial_{\theta_{G}} V\left(\theta_{G}, \theta_{D}\right)=\partial_{\theta_{D}} V\left(\theta_{G}, \theta_{D}\right)=0 \tag{18.7}
\end{equation*}
$$

and

$$
\begin{equation*}
V_{\text {opt }}=\min _{\theta_{G}} \max _{\theta_{D}} V\left(\theta_{G}, \theta_{D}\right) \tag{18.8}
\end{equation*}
$$

Node TPMs for Figs 18.1 and 18.2 are given next in blue:

$$
\begin{gather*}
P\left(\theta_{G}\right)=\text { given }  \tag{18.9}\\
P\left(\theta_{D}\right)=\text { given }  \tag{18.10}\\
P(\vec{u})=\prod_{i} P(u[i]) \text { (usually uniform distribution) }  \tag{18.11}\\
P(\vec{r})=\prod_{i} P(r[i])  \tag{18.12}\\
P\left(f[i] \mid \vec{u}, \theta_{G}\right)=\delta\left[f[i], G\left(u[i], \theta_{G}\right)\right]  \tag{18.13}\\
P\left(c[i] \mid \vec{f}, \theta_{D}\right)=\delta\left(c[i], \bar{D}\left(f[i], \theta_{D}\right)\right)  \tag{18.14}\\
P\left(d[j] \mid \vec{r}, \theta_{D}\right)=\delta\left(d[j], D\left(r[j], \theta_{D}\right)\right)  \tag{18.15}\\
P(V \mid \vec{d}, \vec{c})=\delta\left(V, \frac{1}{N} \ln \prod_{i, j}(c[i] d[j])\right) \tag{18.16}
\end{gather*}
$$

where $N=n \operatorname{sam}(\vec{r}) n \operatorname{sam}(\vec{u})$.
Let $\eta_{G}, \eta_{D}>0$. Maximize $V$ wrt $\theta_{D}$, and minimize it wrt $\theta_{G}$.

$$
\begin{align*}
& P\left(\theta_{G}^{\prime} \mid V, \theta_{G}\right)=\delta\left(\theta_{G}^{\prime}, \theta_{G}-\eta_{G} \partial_{\theta_{G}} V\right)  \tag{18.17}\\
& P\left(\theta_{D}^{\prime} \mid V, \theta_{D}\right)=\delta\left(\theta_{D}^{\prime}, \theta_{D}+\eta_{D} \partial_{\theta_{D}} V\right) \tag{18.18}
\end{align*}
$$

Figure 18.3: GAN, Constraining Bayesian Network
Constraining B net given in Fig 18.3 . It adds 2 new nodes, namely $\underline{\vec{U}}$ and $\underline{\vec{R}}$, to the bnet of Fig 18.1. The purpose of these 2 barren (childrenless) nodes is to constrain certain functions to be probability distributions.

Node TPMs for the 2 new nodes given next in blue.

$$
\begin{equation*}
P\left(U[i] \mid \theta_{G}\right)=\frac{\left.\bar{D}\left(G\left(U[i], \theta_{G}\right), \theta_{D}\right)\right)}{\bar{\lambda}\left(\theta_{G}, \theta_{D}\right)} \tag{18.19}
\end{equation*}
$$

where $S_{\underline{U[i]}}=S_{\underline{u}}$ and $\left.\bar{\lambda}\left(\theta_{G}, \theta_{D}\right)=\sum_{u} \bar{D}\left(G\left(u, \theta_{G}\right), \theta_{D}\right)\right)$.

$$
\begin{equation*}
P\left(R[i] \mid \theta_{G}, \theta_{D}\right)=\frac{D\left(R[i], \theta_{D}\right)}{\lambda\left(\theta_{D}\right)} \tag{18.20}
\end{equation*}
$$

where $S_{\underline{R[i]}}=S_{\underline{r}}$ and $\lambda\left(\theta_{D}\right)=\sum_{r} D\left(r, \theta_{D}\right)$.

$$
\begin{equation*}
P(V \mid \vec{u}, \vec{r})=\delta\left(V, \frac{1}{N} \ln \prod_{i, j}\left(P\left(\underline{R[i]}=r[i] \mid \theta_{G}, \theta_{D}\right) P\left(\underline{U[i]}=u[j] \mid \theta_{G}\right)\right)\right) \tag{18.21}
\end{equation*}
$$

where $N=n \operatorname{sam}(\vec{r}) n \operatorname{sam}(\vec{u})$.
$\mathcal{L}=$ likelihood

$$
\begin{align*}
\mathcal{L} & =P\left(\vec{r}, \vec{u} \mid \theta_{G}, \theta_{D}\right)  \tag{18.22}\\
& =\prod_{i, j}\left[\frac{D\left(r[i], \theta_{D}\right)}{\lambda\left(\theta_{D}\right)} \frac{\left.\bar{D}\left(G\left(u[j], \theta_{G}\right), \theta_{D}\right)\right)}{\bar{\lambda}\left(\theta_{G}, \theta_{D}\right)}\right] \tag{18.23}
\end{align*}
$$

$\ln \mathcal{L}=N\left[V\left(\theta_{G}, \theta_{D}\right)-\ln \lambda\left(\theta_{D}\right)-\ln \bar{\lambda}\left(\theta_{G}, \theta_{D}\right)\right]$

## Chapter 19

## Gaussian Nodes with Linear Dependence on Parents

Bnet nodes that have a Gaussian TPM with a linear dependence on their parent nodes (GLP) are a very popular way of modeling continuous nodes of bnets. A convenient aspect of them is that their parents can be discrete or continuous nodes, and their children can be discrete or continuous nodes too. Also, they can be learned easily from the data because their parameters can be expressed in terms of two node covariances. For these reasons, they are commonly used when doing structure learning of bnets with continuous nodes (see Chapter 49).

Figure 19.1: GLP node $\underline{y}$ with 3 parent nodes $\underline{x}^{3}=\left(\underline{x}_{1}, \underline{x}_{2}, \underline{x}_{3}\right)$.
Recall our notation for a Gaussian distribution:

$$
\begin{equation*}
\mathcal{N}\left(x ; \mu, \sigma^{2}\right)=\frac{1}{\sigma \sqrt{2 \pi}} e^{\frac{-(x-\mu)^{2}}{2 \sigma^{2}}}, \tag{19.1}
\end{equation*}
$$

where $x, \mu \in \mathbb{R}$ and $\sigma>0$.
A GLP node $\underline{y}$ with $n$ parents $\underline{x}^{n}=\left(\underline{x}_{1}, \underline{x}_{2}, \ldots, \underline{x}_{n}\right)$ has the following TPM:

$$
\begin{equation*}
P\left(y \mid x^{n}\right)=\mathcal{N}\left(y ; \beta_{0}+\beta^{n T} x^{n}, \sigma^{2}\right) \tag{19.2}
\end{equation*}
$$

where $\underline{y}, \beta_{0}, \in \mathbb{R}$ and $\sigma^{2}>0$, and where $\underline{x}^{n}, \beta^{n} \in \mathbb{R}^{n}$ are ${ }^{* *}$ column vectors**. The $T$ in $\beta^{n T}$ stands for transpose. Any $\underline{x}_{i}$ can have a discrete set of states as long as
they are real valued and ordinal (ordered by size). Fig 19.1 shows a diagrammatic representation of a GPL node with 3 parents.

Note that as $\sigma \rightarrow 0$, a GLP node becomes deterministic. In fact, it becomes a neural net node with a linear activation function.

An equivalent way of defining a GLP node $y$ is in terms of a random variable equation expressing $\underline{y}$ as a hyperplane function of the parents $\underline{x}^{n}$ plus a Gaussian noise variable. Define an estimator $\underline{\hat{y}}$ of a "true value" $\underline{y}$ by

$$
\begin{equation*}
\underline{\hat{y}}=\beta_{0}+\beta^{n T} \underline{x}^{n} \tag{19.3a}
\end{equation*}
$$

and

$$
\begin{equation*}
\underline{y}=\underline{\hat{y}}+\underline{\epsilon} \tag{19.3b}
\end{equation*}
$$

where the residual $\underline{\epsilon}$ satisfies

$$
\begin{equation*}
P(\epsilon)=\mathcal{N}\left(\epsilon ; 0, \sigma^{2}\right) \tag{19.3c}
\end{equation*}
$$

and

$$
\begin{equation*}
\left\langle\underline{x}^{n}, \underline{\epsilon}\right\rangle=0 . \tag{19.3d}
\end{equation*}
$$

The notation $\langle\underline{x}, \underline{y}\rangle$ for the covariance of random variables $\underline{x}$ and $\underline{y}$ is explained in Chapter Notational Conventions and Preliminaries,

Claim 15 The parameters of a GLP node can be expressed in terms of 2-node covariances. Specifically,

$$
\begin{gather*}
\beta^{n}=\left\langle\underline{x}^{n}, \underline{x}^{n T}\right\rangle^{-1}\left\langle\underline{y}, \underline{x}^{n}\right\rangle  \tag{19.4}\\
\beta_{0}=\langle\underline{y}\rangle-\beta^{n T}\left\langle\underline{x}^{n}\right\rangle  \tag{19.5}\\
\sigma^{2}=\langle\underline{y}, \underline{y}\rangle-\beta^{n T}\left\langle\underline{x}^{n}, \underline{y}\right\rangle \tag{19.6}
\end{gather*}
$$

## proof:

Note that $\left\langle\underline{x}^{n}, \underline{x}^{n T}\right\rangle^{T}=\left\langle\underline{x}^{n}, \underline{x}^{n T}\right\rangle$ and $\left\langle\underline{y}, \underline{x}^{n T}\right\rangle^{T}=\left\langle\underline{y}, \underline{x}^{n}\right\rangle$.

$$
\begin{gather*}
\left\langle\underline{y}, \underline{x}^{n T}\right\rangle=\beta^{n T}\left\langle\underline{x}^{n}, \underline{x}^{n T}\right\rangle  \tag{19.7}\\
\left\langle\underline{y}, \underline{x}^{n}\right\rangle=\left\langle\underline{x}^{n}, \underline{x}^{n T}\right\rangle \beta^{n}  \tag{19.8}\\
\beta^{n}=\left\langle\underline{x}^{n}, \underline{x}^{n T}\right\rangle^{-1}\left\langle\underline{y}, \underline{x}^{n}\right\rangle \tag{19.9}
\end{gather*}
$$

$$
\begin{align*}
\langle\underline{y}\rangle & =\beta_{0}+\beta^{n T}\left\langle\underline{x}^{n}\right\rangle  \tag{19.10}\\
\langle\underline{y}, \underline{y}\rangle & =\left\langle\beta_{0}+\beta^{n T} \underline{x}^{n}+\underline{\epsilon}, \underline{y}\right\rangle  \tag{19.11}\\
& =\beta^{n T}\left\langle\underline{x}^{n}, \underline{y}\right\rangle+\sigma^{2} \tag{19.12}
\end{align*}
$$

## QED

Let $\mathrm{D}=$ Discrete, $\mathrm{GLP}=$ Gaussian with Linear dependence in Parents The following arrows are possible in a bnet.

- $G L P \leftarrow G L P$
- $G L P \leftarrow D$

Pass to GLP a separate set of regression coefficients $\beta_{0}, \beta^{n}$ and variance $\sigma^{2}$ for each state of D . If D is called $\underline{d}$, let

$$
\begin{equation*}
P\left(y \mid\left(x^{n}\right)_{d}, d\right)=\mathcal{N}\left(y ;\left(\beta_{0}\right)_{d}+\left(\beta^{n T}\right)_{d}\left(x^{n}\right)_{d}, \sigma_{d}^{2}\right) \tag{19.13}
\end{equation*}
$$

for each $d \in S_{\underline{d}}$.

- $D \leftarrow G L P$

If D expects a continuous parent, no need to preprocess GLP output. If D expects a discrete parent, break the interval $[a, b]$ that contains most of the range of the GPL node into sub-intervals and assign a discrete label to each subinterval.

- $D \leftarrow D$

## Chapter 20

## Hidden Markov Model

A Hidden Markov Model (HMM) is a generalization of a Kalman Filter (KF). KFs are discussed in Chapter 25. The bnets of HHMs and KFs bnets are the same. The only difference is that a KF assumes special node TPMs.

See Wikipedia article Ref. [56] to learn about the history and many uses of HMMs. This chapter is based on Ref.[20].

Figure 20.1: HMM bnet with $n=4$.
Suppose
$\underline{v}^{n}=\left(\underline{v}_{0}, \underline{v}_{1}, \ldots, \underline{v}_{n-1}\right)$ are $n$ visible nodes that are measured, and
$\underline{x}^{n}=\left(\underline{x}_{0}, \underline{x}_{1}, \ldots, \underline{x}_{n-1}\right)$ are the $n$ hidden, unmeasurable state nodes of a system that is being monitored.

For the bnet of Fig.20.1, one has

$$
\begin{equation*}
P\left(x^{n}, v^{n}\right)=\prod_{i=0}^{n-1} P\left(x_{i} \mid x_{i-1}\right) P\left(v_{i} \mid x_{i}\right) \tag{20.1}
\end{equation*}
$$

where $x_{-1}=0$.
Let $x_{<i}=\left(x_{0}, x_{1}, \ldots, x_{i-1}\right)$.
For $i=0,1, \ldots, n-1$, define
$\mathcal{F}_{i}=$ future measurements probability

$$
\begin{equation*}
\mathcal{F}_{i}\left(x_{i}\right)=P\left(v_{>i} \mid x_{i}\right) \tag{20.2}
\end{equation*}
$$

$\overline{\mathcal{F}}_{i}=$ past and present measurements probability

$$
\begin{equation*}
\overline{\mathcal{F}}_{i}\left(x_{i}\right)=P\left(v_{<i}, v_{i}, x_{i}\right) \tag{20.3}
\end{equation*}
$$

$\lambda_{i}=$ present measurement probability

$$
\begin{equation*}
\lambda_{i}\left(x_{i}\right)=P\left(v_{i} \mid x_{i}\right) \tag{20.4}
\end{equation*}
$$

$\mathcal{F}_{i}, \overline{\mathcal{F}}_{i}$ and $\lambda_{i}$ can be represented graphically as follows:

$$
\begin{gather*}
\mathcal{F}_{i}\left(x_{i}\right)=\frac{1}{P\left(x_{i}\right)} \sum_{x_{>i}} \quad x_{i} \longrightarrow x_{>i}  \tag{20.5}\\
\overline{\mathcal{F}}_{i}\left(x_{i}\right)=\sum_{x_{<i}} \quad x_{<i} \longrightarrow x_{i}  \tag{20.6}\\
\lambda_{i}\left(x_{i}\right)=\frac{1}{P\left(x_{i}\right)}  \tag{20.7}\\
v_{<i} \\
x_{i} \\
v_{i}
\end{gather*}
$$

Claim 16 For $i \geq 0$,

$$
\begin{equation*}
P\left(x_{i}, v^{n}\right)=\overline{\mathcal{F}}_{i}\left(x_{i}\right) \mathcal{F}_{i}\left(x_{i}\right) . \tag{20.8}
\end{equation*}
$$

For $i>0$,

$$
\begin{equation*}
P\left(x_{i-1}, x_{i}, v^{n}\right)=\overline{\mathcal{F}}_{i-1}\left(x_{i-1}\right) \lambda_{i}\left(x_{i}\right) P\left(x_{i} \mid x_{i-1}\right) \mathcal{F}_{i}\left(x_{i}\right) . \tag{20.9}
\end{equation*}
$$

## proof:

$$
\begin{align*}
P\left(x_{i}, v^{n}\right) & =\sum_{x_{<i}} \sum_{x_{>i}} P\left(x^{n}, v^{n}\right)  \tag{20.10}\\
& =\sum_{x_{<i}} \sum_{x_{>i}} P\left(x^{n}, v^{n} \mid x_{i}\right) P\left(x_{i}\right)  \tag{20.11}\\
& =\sum_{x_{<i}} \sum_{x_{>i}} P\left(x_{<i}, v_{<i}, v_{i} \mid x_{i}\right) P\left(x_{>i}, v_{>i} \mid x_{i}\right) P\left(x_{i}\right)  \tag{20.12}\\
& =P\left(v_{<i}, v_{i} \mid x_{i}\right) P\left(v_{>i} \mid x_{i}\right) P\left(x_{i}\right)  \tag{20.13}\\
& =\overline{\mathcal{F}}_{i}\left(x_{i}\right) \mathcal{F}_{i}\left(x_{i}\right) \tag{20.14}
\end{align*}
$$

$$
\begin{align*}
P\left(x_{i-1}, x_{i}, v^{n}\right) & =\sum_{x_{<i-1}} \sum_{x_{>i}} P\left(x^{n}, v^{n}\right)  \tag{20.15}\\
& =\sum_{x_{<i-1}} \sum_{x_{>i}} P\left(x^{n}, v^{n} \mid x_{i-1}, x_{i}\right) P\left(x_{i-1}, x_{i}\right)  \tag{20.16}\\
& =\sum_{x_{<i-1}} \sum_{x_{>i}} P\left(x_{<i-1}, v_{<i-1}, v_{i-1} \mid x_{i-1}\right) P\left(v_{i} \mid x_{i}\right) P\left(x_{i-1}, x_{i}\right) P\left(x_{>i}, v_{>i} \mid x_{i}\right)  \tag{20.17}\\
& =P\left(v_{<i-1}, v_{i-1} \mid x_{i-1}\right) P\left(v_{i} \mid x_{i}\right) P\left(x_{i-1}, x_{i}\right) P\left(v_{>i} \mid x_{i}\right)  \tag{20.18}\\
& =\overline{\mathcal{F}}_{i-1}\left(x_{i-1}\right) \lambda_{i}\left(x_{i}\right) P\left(x_{i} \mid x_{i-1}\right) \mathcal{F}_{i}\left(x_{i}\right) \tag{20.19}
\end{align*}
$$

QED
Claim 17 For $i>0, \mathcal{F}_{i}$ and $\overline{\mathcal{F}}_{i}$ can be calculated recursively as follows:

$$
\begin{align*}
& \overline{\mathcal{F}}_{i}\left(x_{i}\right)=\sum_{x_{i-1}} \overline{\mathcal{F}}_{i-1}\left(x_{i-1}\right) \lambda_{i}\left(x_{i}\right) P\left(x_{i} \mid x_{i-1}\right)  \tag{20.20}\\
& \mathcal{F}_{i-1}\left(x_{i-1}\right)=\sum_{x_{i}} \lambda_{i}\left(x_{i}\right) P\left(x_{i} \mid x_{i-1}\right) \mathcal{F}_{i}\left(x_{i}\right) \tag{20.21}
\end{align*}
$$

proof:

$$
\begin{align*}
\overline{\mathcal{F}}_{i}\left(x_{i}\right) \mathcal{F}_{i}\left(x_{i}\right) & =P\left(x_{i}, v^{n}\right)  \tag{20.22}\\
& =\sum_{x_{i-1}} P\left(x_{i-1}, x_{i}, v^{n}\right)  \tag{20.23}\\
= & \sum_{x_{i-1}} \overline{\mathcal{F}}_{i-1}\left(x_{i-1}\right) \lambda_{i}\left(x_{i}\right) P\left(x_{i} \mid x_{i-1}\right) \mathcal{F}_{i}\left(x_{i}\right)  \tag{20.24}\\
\overline{\mathcal{F}}_{i-1}\left(x_{i-1}\right) \mathcal{F}_{i-1}\left(x_{i-1}\right) & =P\left(x_{i-1}, v^{n}\right)  \tag{20.25}\\
& =\sum_{x_{i}} P\left(x_{i-1}, x_{i}, v^{n}\right)  \tag{20.26}\\
& =\sum_{x_{i}} \overline{\mathcal{F}}_{i-1}\left(x_{i-1}\right) \lambda_{i}\left(x_{i}\right) P\left(x_{i} \mid x_{i-1}\right) \mathcal{F}_{i}\left(x_{i}\right) \tag{20.27}
\end{align*}
$$

QED

Claim 18

$$
\begin{gather*}
P\left(x_{i} \mid x_{i-1}, v^{n}\right)=\frac{\lambda_{i}\left(x_{i}\right) \mathcal{F}_{i}\left(x_{i}\right)}{\mathcal{F}_{i-1}\left(x_{i-1}\right)} P\left(x_{i} \mid x_{i-1}\right)  \tag{20.28}\\
P\left(x_{i-1} \mid x_{i}, v^{n}\right)=\frac{\lambda_{i}\left(x_{i}\right) \overline{\mathcal{F}}_{i-1}\left(x_{i-1}\right)}{\overline{\mathcal{F}}_{i}\left(x_{i}\right)} P\left(x_{i} \mid x_{i-1}\right) \tag{20.29}
\end{gather*}
$$

proof:

$$
\begin{align*}
P\left(x_{i} \mid x_{i-1}, v^{n}\right) & =\frac{P\left(x_{i-1}, x_{i}, v^{n}\right)}{P\left(x_{i-1}, v^{n}\right)}  \tag{20.30}\\
& =\frac{\overline{\mathcal{F}}_{i-1}\left(x_{i-1}\right) \lambda_{i}\left(x_{i}\right) P\left(x_{i} \mid x_{i-1}\right) \mathcal{F}_{i}\left(x_{i}\right)}{\overline{\mathcal{F}}_{i-1}\left(x_{i-1}\right) \mathcal{F}_{i-1}\left(x_{i-1}\right)} \tag{20.31}
\end{align*}
$$

Analogous proof for Eq. 20.29).
QED

## Chapter 21

## Influence Diagrams \& Utility Nodes

Influence diagrams are just arbitrary bnets enhanced with a new kind of node called an utility node. The rest of this brief chapter will be devoted to discussing utility nodes.

Suppose $U(x)$ is a deterministic function $U: S_{\underline{x}} \rightarrow \mathbb{R}$ called the utility function. Then the expected utility is defined as

$$
\begin{align*}
E_{\underline{U}}[\underline{U}] & =\sum_{U} P(U) U  \tag{21.1}\\
& =\sum_{x} \sum_{U} \underbrace{P(U \mid x)}_{\delta[U, U(x)]} P(x) U  \tag{21.2}\\
& =\sum_{x} P(x) U(x) \tag{21.3}
\end{align*}
$$

An utility node can be understood as a node composed of 3 simpler bnet nodes. This is illustrated in Fig 21.1.

Figure 21.1: An utility node can be understood as a node composed of 3 simpler bnet nodes.

The TPMs, printed in blue, for the nodes of Fig 21.1, are as follows:

$$
\begin{equation*}
P(U \mid p a(U))=\delta[U, U(p a(U))] \tag{21.4}
\end{equation*}
$$

where if $U: S_{\underline{x}} \rightarrow \mathbb{R}$, then $\underline{x}=p a(\underline{U})$.

$$
\begin{equation*}
P(u \mid p a(U))=\delta[u, U(p a(U))] \tag{21.5}
\end{equation*}
$$

Node $\underline{\mu}_{u}$ calculates the expected value (mean value) of $\underline{u}$ :

$$
\begin{equation*}
P\left(\mu_{u}\right)=\delta\left(\mu_{u}, E_{\underline{u}}[\underline{u}]\right) \tag{21.6}
\end{equation*}
$$

Node $\underline{\sigma}_{u}$ calculates the standard deviation of $\underline{u}$ :

$$
\begin{equation*}
P\left(\sigma_{u}\right)=\delta\left(\sigma_{U}, \sqrt{E_{\underline{u}}\left[\left(\underline{u}-E_{\underline{u}}[\underline{u}]\right)^{2}\right]}\right) \tag{21.7}
\end{equation*}
$$

Note that in order to calculate expected values, it is necessary that $\underline{U}, \underline{u} \in \mathbb{R}$. Note that nodes $\underline{u}, \underline{\mu}_{u}, \underline{\sigma}_{u}$ must all 3 have access to the TPM $P(U \mid p a(U))$ of node $\underline{U}$. In fact, in order to calculate $E_{\underline{u}}[\cdot]$, it is necessary for nodes $\underline{\mu}_{u}$ and $\underline{\sigma}_{u}$ to have access not just to $P(U \mid p a(U))$ but also to $P(p a(U))$.

See Fig. 21.2. An influence diagram may have multiple utility nodes $\left(\underline{U}_{1}\right.$ and $\underline{U}_{2}$ in Fig.21.2). Then one can define a merging utility node $\underline{U}$ that sums the values of all the other utility nodes.

Figure 21.2: An influence diagram may have multiple utility nodes, say $\underline{U}_{1}$ and $\underline{U}_{2}$. Then one can define an utility node $\underline{U}=\underline{U}_{1}+\underline{U}_{2}$.

For the node $\underline{U}$ of $\operatorname{Fig} 21.2$,

$$
\begin{equation*}
P\left(U \mid U_{1}, U_{2}\right)=\delta\left(U, U_{1}+U_{2}\right) \tag{21.8}
\end{equation*}
$$

## Chapter 22

## Instrumental Inequality and beyond

This chapter is based on Refs. (4] and [23].
Instrumental Variables (IVs) are discussed in Chapter 23. This chapter will discuss the original Instrumental inequality (I-inequality) discovered by Pearl, and other related inequalities. The I-inequality arises in bnets that use an IV. The Iinequality bounds the effect that an IV $\underline{z}$ can have on the outcome $\underline{y}$ of a treatment $\underline{d} \rightarrow \underline{y}$. Since there is a path $\underline{z} \rightarrow \underline{d} \rightarrow \underline{y}$, the treatment dose $\underline{d}$ acts as a mediator between the IV $\underline{z}$ and the treatment outcome $\underline{y}$. The I-inequality is reminiscent of the data processing inequality $H(\underline{z}: \underline{y}) \leq H(\underline{d}: \underline{y})$ which is valid for a simple Markov chain bnet $\underline{z} \rightarrow \underline{d} \rightarrow \underline{y}$. The data processing inequality is saying that the endpoint $\underline{y}$ receives more information from $\underline{d}$ than from $\underline{z}$. This is reasonable, since $\underline{y}$ is "closer" to $\underline{d}$ than to $\underline{z}$.

### 22.1 I-inequality

Figure 22.1: In bnet $G$, an IV $\underline{z}$ acts on a treatment $\underline{d} \rightarrow \underline{y}$. Bnet $\tilde{G}$ is obtained by applying an imagine operator to arrow $\underline{d} \rightarrow \underline{y}$ of bnet $G$.

Claim 19 The TPMs for the bnet $G$ in Fig 22.1 satisfy

$$
\begin{equation*}
\max _{d} \sum_{y} \max _{z} P(d, y \mid z) \leq 1 \tag{22.1}
\end{equation*}
$$

proof:
Below, any probability that alludes to a value $\tilde{d}$ refers to bnet $\tilde{G}$. Otherwise, if it doesn't allude to $\tilde{d}$, then it refers to $G$ (or to $\tilde{G}$, since the TPMs of $\tilde{G}$ are defined from those of $G$ in a consistent manner.)
$G$ satisfies

$$
\begin{equation*}
P(d, y \mid z)=\sum_{u} P(u) P(y \mid u, d) P(d \mid u, z), \tag{22.2}
\end{equation*}
$$

and $\tilde{G}$ satisfies

$$
\begin{equation*}
P(d, y \mid z, \tilde{d})=\sum_{u} P(u) P(y \mid u, \tilde{d}) P(d \mid u, z) . \tag{22.3}
\end{equation*}
$$

Note that Eqs. 22.2 and (22.3) imply that

$$
\begin{equation*}
P(d, y \mid z, d)=P(d, y \mid z) \tag{22.4}
\end{equation*}
$$

and that

$$
\begin{equation*}
P(\tilde{d}, y \mid z, \tilde{d}) \leq \sum_{d} P(d, y \mid z, \tilde{d})=P(y \mid \tilde{d}) \tag{22.5}
\end{equation*}
$$

Thus,

$$
\begin{align*}
\max _{\tilde{d}} \sum_{y} \max _{z} P(\tilde{d}, y \mid z, \tilde{d}) & \leq \max _{\tilde{d}} \sum_{y} \max _{z} P(y \mid \tilde{d})  \tag{22.6}\\
& \leq \max _{\tilde{d}} \sum_{y} P(y \mid \tilde{d})  \tag{22.7}\\
& \leq \max _{\tilde{d}} 1  \tag{22.8}\\
& \leq 1 \tag{22.9}
\end{align*}
$$

## QED

As pointed out in Ref. [4] from which I learned the above proof, the above proof is highly generalizable.

Fig 22.2 gives a graphical representation of the boxed Eq. 22.5) which is crucial to the proof.

And here is a meta-description of the steps in the proof:

Figure 22.2: Graphical representation of the boxed equation Eq. 22.5.

1. Use imagine operator to create a non-negative matrix $M_{d, \tilde{d}}$.
2. Use fact that row or column sum of $M_{d, \tilde{d}}$ is larger than diagonal element in sum: $\sum_{d} M_{d, \tilde{d}} \geq M_{\tilde{d}, \tilde{d}}$.

### 22.1.1 I-inequality for binary $\mathrm{z}, \mathrm{d}, \mathrm{y}$

It is enlightening to write down the I-inequality for the special case that $\underline{z}, \underline{d}, \underline{y}$ are binary.

$$
\begin{aligned}
& P(d=1, y \mid z)=\begin{array}{r} 
\\
z=0 \\
y=0 \\
\begin{array}{l}
z=1 \\
\hline a \\
\hline \\
y=1 \\
\hline c
\end{array} \\
\hline
\end{array} \\
& a+d \leq 1 \\
& b+c \leq 1
\end{aligned}
$$

Figure 22.3: I-inequality for binary $\underline{z}, \underline{d}, \underline{y}$. The same picture except with $d=0$ is also true.

In the binary case, the I-inequality implies 4 different inequalities. These are as follows. One gets two inequalities by setting $d=1$ in the next 2 equations.

$$
\begin{align*}
& \sum_{y=0}^{1} \sum_{z=0}^{1} \mathbb{1}(y=z) P(d, y \mid z),  \tag{22.10a}\\
& \sum_{y=0}^{1} \sum_{z=0}^{1} \mathbb{1}(y \neq z) P(d, y \mid z) . \tag{22.10b}
\end{align*}
$$

One gets an additional 2 inequalities by setting $d=0$ in Eqs. 22.10). These 4 inequalities are illustrated in Fig.22.3.

What do they mean? That at fixed $\underline{d}$, the correlation between $\underline{z}$ and $\underline{y}$ is limited.

### 22.2 Bounds on Effect of IV on treatment outcome y

Figure 22.4: Bnet $\mathcal{G}$ is obtained from the bnet $G$ in Fig 22.1 by adding to $G$ an arrow from the IV $\underline{z}$ to the treatment outcome $\underline{y}$. Bnet $\mathcal{G}_{\text {do }}$ is obtained by applying a do operator to node $\underline{d}$ of $\mathcal{G}$. Bnet $\mathcal{G}_{i m}$ is obtained by applying an imagine operator to arrow $\underline{d} \rightarrow \underline{y}$ of $\mathcal{G}$.

In this section, we will assume that random variables $\underline{z}, \underline{d}, \underline{y}$ are binary. Just as with the binary case of the I-inequality, we will find an inequality for each value of $\underline{d} \in\{0,1\}$.

Below, we will use the following 3 shorthand notations:

$$
\begin{gather*}
P_{y \mid z}(d)=P(d, y \mid z)  \tag{22.11}\\
P_{\mid z}(d)=\sum_{y} P(d, y \mid z) \tag{22.12}
\end{gather*}
$$

and

$$
\begin{equation*}
\pi_{\mid z}(d)=1-P_{\mid z}(d) \tag{22.13}
\end{equation*}
$$

For the bnet $\mathcal{G}_{d o}$ in Fig 22.4, define the IV effect at fixed $\rho \underline{d}=\tilde{d}$ by

$$
\begin{equation*}
\operatorname{IVE}(\tilde{d})=P(y=1 \mid z=1, \rho \underline{d}=\tilde{d})-P(y=1 \mid z=0, \rho \underline{d}=\tilde{d}) \tag{22.14}
\end{equation*}
$$

Claim 20 The TPMs for the bnet $\mathcal{G}_{\text {do }}$ in Fig 22.4 satisfy

$$
\begin{equation*}
\pi_{\mid 0}(d) \leq\left[\operatorname{IVE}(d)-\left\{P_{1 \mid 1}(d)-P_{1 \mid 0}(d)\right\}\right] \leq \pi_{\mid 1}(d) \tag{22.15}
\end{equation*}
$$

## proof:

$$
\begin{align*}
P(y \mid z, \rho \underline{d}=\tilde{d}) & =\sum_{u} P(u) P(y \mid u, z, \tilde{d})  \tag{22.16}\\
& =\sum_{u} P(u) \sum_{d} P(d, y \mid u, z, \tilde{d})  \tag{22.17}\\
& \geq \sum_{u} P(u) P(\tilde{d}, y \mid u, z, \tilde{d})  \tag{22.18}\\
& =\sum_{u}^{u} P(u) P(\tilde{d}, y \mid u, z)  \tag{22.19}\\
& =P_{y \mid z}(\tilde{d}) \tag{22.20}
\end{align*}
$$

Next note that $P(d, y \mid z, \tilde{d}) \geq 0$, and $\sum_{d, y} P(d, y \mid z, \tilde{d})=1$. If we write a table for $P(d, y \mid z, \tilde{d})$ at fixed $z, \tilde{d}$ with row and column indices $(d, y)$, then a partial sum of the entries of that table must be $\leq 1$ :

$$
\begin{equation*}
\sum_{d \neq \tilde{d}} P(d, y \mid z, \tilde{d})+\underbrace{\sum_{y^{\prime}} P\left(\tilde{d}, y^{\prime} \mid z, \tilde{d}\right)}_{P_{\mid z}(\tilde{d})} \leq 1 \tag{22.21}
\end{equation*}
$$

Using the definitions of $P_{\mid z}$ and $\pi_{\mid z}$, we can rewrite the last equation as

$$
\begin{equation*}
\sum_{d \neq \tilde{d}} P(d, y \mid z, \tilde{d}) \leq \pi_{\mid z}(\tilde{d}) \tag{22.22}
\end{equation*}
$$

Next note that

$$
\begin{align*}
P(y \mid z, \rho \underline{d}=\tilde{d}) & =\sum_{u} P(u) P(y \mid u, z, \tilde{d})  \tag{22.23}\\
& =\sum_{u} P(u) \sum_{d} P(d, y \mid u, z, \tilde{d})  \tag{22.24}\\
& =P(\tilde{d}, y \mid z, \tilde{d})+\sum_{d \neq \tilde{d}} P(d, y \mid z, \tilde{d})  \tag{22.25}\\
& =P_{y \mid z}(\tilde{d})+\sum_{d \neq \tilde{d}} P(d, y \mid z, \tilde{d})  \tag{22.26}\\
& \leq P_{y \mid z}(\tilde{d})+\pi_{\mid z}(\tilde{d}) \tag{22.27}
\end{align*}
$$

Hence,

$$
\begin{equation*}
P_{y \mid z}(\tilde{d}) \leq P(y \mid z, \rho \underline{d}=\tilde{d}) \leq P_{y \mid z}(\tilde{d})+\pi_{\mid z} \tag{22.28}
\end{equation*}
$$

$$
\begin{gather*}
P_{1 \mid 1}(\tilde{d}) \leq P(y=1 \mid z=1, \rho \underline{d}=\tilde{d}) \leq P_{1 \mid 1}(\tilde{d})+\pi_{\mid 1}  \tag{22.29}\\
-P_{1 \mid 0}(\tilde{d})-\pi_{\mid 0} \leq-P(y=1 \mid z=0, \rho \underline{d}=\tilde{d}) \leq-P_{1 \mid 0}(\tilde{d}) \tag{22.30}
\end{gather*}
$$

QED

## Chapter 23

## Instrumental Variables

This chapter is based on Refs. 3] and 58].
The theory of potential outcomes (PO) discussed in Chapter 39 assumes that confounders can be ignored by conditioning on them. However, there are cases when that is not possible, as when there are some unmeasured (i.e., unobserved, hidden) confounder nodes in the bnet, because one can only condition on observed random variables, by definition. So what if confounders can't be ignored? Are we then precluded from using PO theory? Not necessarily. It might still be possible to use PO theory if one can find a suitable instrumental variable (IV) for the problem.

IVs were actually invented by Sewall Wright and his father Philip Wright long before PO theory was invented by Rubin. The reason why IVs save PO theory is greatly clarified by using Pearl causal DAGs and his d-separation theorem (see Chapter 14).

Most of the discussion in this chapter is limited to LDEN (linear deterministic bnets with external noise). These are discussed in Chapter 27. However, as will become obvious to the reader, IVs are also applicable and useful in general bnet modeling.

## $23.1 \delta$ with unnmeasured confounder

In this section, we explain using LDENs why unmeasured confounders prejudice PO calculations.

Figure 23.1: An LDEN bnet. The direct path $\underline{d} \rightarrow \underline{y}$ is confounded by a hidden variable $\underline{h}$.

Consider the LDEN bnet of Fig,23.1, For some $\delta, \mu \in \mathbb{R}$, we have

$$
\begin{equation*}
\underline{y}=\delta \underline{d}+\underbrace{\mu \underline{h}+\underline{u}_{y}}_{\underline{n}_{y}} . \tag{23.1}
\end{equation*}
$$

If $\left\langle\underline{n}_{\underline{y}}, \underline{d}\right\rangle=0$, then

$$
\begin{equation*}
\langle\underline{y}, \underline{d}\rangle=\delta_{0}\langle\underline{d}, \underline{d}\rangle, \tag{23.2}
\end{equation*}
$$

whereas if $\left\langle\underline{n_{y}}, \underline{d}\right\rangle \neq 0$, then

$$
\begin{equation*}
\langle\underline{y}, \underline{d}\rangle=\delta_{1}\langle\underline{d}, \underline{d}\rangle+\left\langle\underline{n_{y}}, \underline{d}\right\rangle . \tag{23.3}
\end{equation*}
$$

Therefore,

$$
\begin{gather*}
\delta_{0}=\frac{\langle\underline{y}, \underline{d}\rangle}{\langle\underline{d}, \underline{d}\rangle},  \tag{23.4}\\
\delta_{1}=\underbrace{\frac{\langle\underline{y}, \underline{d}\rangle}{\langle\underline{d}, \underline{d}\rangle}}_{\delta_{0}}-\frac{\left\langle\underline{n_{y}}, \underline{d}\right\rangle}{\langle\underline{d}, \underline{d}\rangle} . \tag{23.5}
\end{gather*}
$$

If we assume no confounders and there is one, this gives the difference between the estimate $\delta_{1}$ of $\delta$ for the truth, versus the naive estimate $\delta_{0}$.

If the confounder $\underline{h}$ had been measured, then we would calculate the covariances at fixed $\underline{n}_{\underline{y}}$, and the conditional covariance $\left\langle\underline{n}_{\underline{y}}, \underline{d}\right\rangle_{\mid \underline{n}_{\underline{y}}}=0$

## $23.2 \delta$ (with unmeasured confounder) can be inferred via IV

Figure 23.2: Two LDEN bnets. The direct path $\underline{d} \rightarrow \underline{y}$ is confounded by a hidden variable $\underline{h}$, but by using the IV $\underline{A}$, we are still able to identify (i.e. calculate) $\delta$.

Now consider the two LDEN bnets shown in Fig 23.2. Note that there are no arrows $\underline{A} \rightarrow \underline{y}$ or $\underline{A} \rightarrow \underline{h}$. Note that node $\underline{d}$ is a collider in the path $\underline{A}-\underline{d}-\underline{h}-\underline{y}$, Therefore, the only unblocked path from $\underline{A}$ to $\underline{y}$ in $G$ is $\underline{A} \rightarrow \underline{d} \rightarrow \underline{y}$ and that path has been removed in $G_{i m+}$. These observations are encapsulated in the following statements.

$$
\begin{gather*}
\underline{d} \perp_{G} \underline{y}=\text { false, } \underline{A} \perp_{G} \underline{y}=\text { false } .  \tag{23.6}\\
\underline{d} \perp_{G_{i m+}} \underline{y}=\text { false, } \underline{A} \perp_{G_{i m+}} \underline{y}=\text { true } . \tag{23.7}
\end{gather*}
$$

The following is true for $G$ :

$$
\begin{align*}
& \underline{y}=\delta \underline{d}+\underbrace{\mu \underline{h}+\underline{u}_{y}}_{\underline{n}_{\underline{y}}}  \tag{23.8}\\
& \underline{d}=\alpha \underline{A}+\underbrace{\nu \underline{h}+\underline{u}_{d}}_{\underline{n}_{\underline{d}}} \tag{23.9}
\end{align*}
$$

Since $\left\langle\underline{n}_{\underline{y}}, \underline{A}\right\rangle=\left\langle\underline{n}_{\underline{d}}, \underline{A}\right\rangle=0$ is true in $G$, we have

$$
\begin{equation*}
\langle\underline{y}, \underline{A}\rangle=\delta\langle\underline{d}, \underline{A}\rangle \tag{23.10}
\end{equation*}
$$

and

$$
\begin{equation*}
\langle\underline{d}, \underline{A}\rangle=\alpha\langle\underline{A}, \underline{A}\rangle . \tag{23.11}
\end{equation*}
$$

Note that $\langle\underline{y}, \underline{A}\rangle=\delta=0$ for $G_{i m+}$ but not for $G$, so we are speaking about $G$ from here on. It follows that

$$
\begin{equation*}
\alpha=\frac{\langle\underline{d}, \underline{A}\rangle}{\langle\underline{A}, \underline{A}\rangle} \tag{23.12}
\end{equation*}
$$

and

$$
\begin{align*}
\delta & =\frac{\langle\underline{y}, \underline{A}\rangle}{\langle\underline{d}, \underline{A}\rangle}  \tag{23.13}\\
& =\frac{\langle\underline{y}, \underline{A}\rangle}{\langle\underline{A}, \underline{A}\rangle} \frac{\langle\underline{A}, \underline{A}\rangle}{\langle\underline{d}, \underline{A}\rangle}  \tag{23.14}\\
& =\frac{\langle\underline{y}, \underline{A}\rangle}{\langle\underline{A}, \underline{A}\rangle} \frac{1}{\alpha}  \tag{23.15}\\
& =\frac{\langle\underline{y}, \alpha \underline{A}\rangle}{\langle\alpha \underline{A}, \alpha \underline{A}\rangle} \tag{23.16}
\end{align*}
$$

### 23.3 More general bnets with IVs

Figure 23.3: The 2 paths in $G_{i m+}$ from IV variable $\underline{A}$ to $y$ are blocked by colliders $\underline{v}$ and $\underline{d}$. Thus, $\underline{d} \perp_{G_{i m+}} \underline{y}=$ false, $\underline{A} \perp_{G_{i m+}} \underline{y}=$ true

Figure 23.4: There are 2 paths in $G_{i m+}$ from IV variable $\underline{A}$ to $\underline{y}$. One is blocked by the collider $\underline{d}$ and the other can be blocked by conditioning on $\underline{v}$. Thus, $\underline{d} \perp_{G_{i m+}}$ $\underline{y} \mid \underline{v}=$ false, $\underline{A} \perp_{G_{i m+}} \underline{y} \mid \underline{v}=$ true

Figs 23.3 and 23.4 are examples of other bnets for which the effect $\delta$ is identifiable thanks to the IV $\underline{A}$.

### 23.4 Instrumental Inequality

Pearl's instrumental inequality and related inequalities are discussed in Chapter 22.

## Chapter 24

## Junction Tree Algorithm

The Junction Tree (JT) algorithm is an algo for evaluating exact marginals of a bnet, including cases in which some nodes are fixed to a single state. (fixed nodes are called the a priori evidence.)

The JT algo starts by clustering the loops of a bnet into bigger nodes so as to transform the bnet into a polytree bnet. Then it applies Pearl Belief Propagation (see Chapter 31) to the ensuing polytree. The first breakthrough paper to achieve this agenda in full was Ref. [13] by Lauritzen, and Spiegelhalter in 1988. See the Wikipedia article Ref. 60 for more info and references on the JT algorithm.

I won't describe the JT algo any further here, because it would take too long for this brief book to give a complete treatment of it, including the mathematical proofs. If all you want to do is to code the JT algo, without delving into the mathematical theorems and proofs behind it, I strongly recommend Ref.[12]. Ref.[12] is an excellent cookbook for programmers of the JT algo. My open source program QuantumFog (see Ref. [40]) implements the JT algo in Python, following the recipe of Ref.[12].

## Chapter 25

## Kalman Filter

A Kalman Filter is a special case of a Hidden Markov Model. HMMs are discussed in Chapter 20.

Figure 25.1: Kalman Filter bnet with $T=4$.
Let $t=0,1,2, \ldots, T-1$.
$\underline{x}_{t} \in S_{\underline{x}}$ are random variables that represent the hidden (unobserved) true state of the system.
$\underline{z}_{t} \in S_{\underline{z}}$ are random variables that represent the measured (observed) state of the system.

The Kalman Filter bnet Fig 25.1 has the following node TPMs, printed in blue:

$$
\begin{equation*}
P\left(x_{t} \mid x_{t-1}\right)=\mathcal{N}\left(x_{t} ; F_{t} x_{t-1}+B_{t} u_{t}, Q_{t}\right), \tag{25.1}
\end{equation*}
$$

where $F_{t}, Q_{t}, B_{t}, u_{t}$ are given. $P\left(x_{t} \mid x_{t-1}\right)$ becomes $P\left(x_{t}\right)$ for $t=0$.

$$
\begin{equation*}
P\left(z_{t} \mid x_{t}\right)=\mathcal{N}\left(z_{t} ; H_{t} x_{t}, R_{t}\right) \tag{25.2}
\end{equation*}
$$

where $H_{t}, R_{t}$ are given.
Define

$$
\begin{equation*}
\underline{Z}_{t}=\left(\underline{z}_{t^{\prime}}\right)_{t^{\prime} \leq t} . \tag{25.3}
\end{equation*}
$$

Define $\hat{x}_{t}$ and $P_{t}$ by

$$
\begin{equation*}
P\left(x_{t} \mid Z_{t}\right)=\mathcal{N}\left(x_{t} ; \hat{x}_{t}, P_{t}\right) . \tag{25.4}
\end{equation*}
$$

### 25.1 Problem

Find $\hat{x}_{t}$ and $P_{t}$ in terms of

1. current (at time $t$ ) given values of $F, Q, H, R, B, u$
2. current (at time $t$ ) observed value of $z$
3. prior (previous) value (at time $t-1$ ) of $\hat{x}$ and $P$.

See Fig 25.2. For that figure,

$$
\begin{equation*}
P\left(\hat{x}_{t}, P_{t} \mid z_{t}, \hat{x}_{t-1}, P_{t-1}\right)=\delta\left(\hat{x}_{t}, ?\right) \delta\left(P_{t}, ?\right) \tag{25.5}
\end{equation*}
$$

Figure 25.2: Kalman Filter bnet with deterministic nodes for $\hat{x}_{t}, P_{t}$.

### 25.2 Solution

Solution copied from Wikipedia Ref. 62].
Define $\eta_{t \mid t}=\eta_{t}$ for $\eta=\hat{x}, P$.

## - Predict

Predicted (a priori) state estimate

$$
\begin{equation*}
\hat{x}_{t \mid t-1}=F_{t} \hat{x}_{t-1 \mid t-1}+B_{t} u_{t} \tag{25.6}
\end{equation*}
$$

Predicted (a priori) estimate covariance

$$
\begin{equation*}
P_{t \mid t-1}=F_{t} P_{t-1 \mid t-1} F_{t}^{\top}+Q_{t} \tag{25.7}
\end{equation*}
$$

## - Update

Innovation (or measurement pre-fit residual)

$$
\begin{equation*}
\tilde{y}_{t \mid t-1}=z_{t}-H_{t} \hat{x}_{t \mid t-1} \tag{25.8}
\end{equation*}
$$

Innovation (or pre-fit residual) covariance

$$
\begin{equation*}
S_{t}=H_{t} P_{t \mid t-1} H_{t}^{\top}+R_{t} \tag{25.9}
\end{equation*}
$$

Optimal Kalman gain

$$
\begin{equation*}
K_{t}=P_{t \mid t-1} H_{t}^{\top} S_{t}^{-1} \tag{25.10}
\end{equation*}
$$

Updated (a posteriori) state estimate

$$
\begin{equation*}
\hat{x}_{t \mid t}=\hat{x}_{t \mid t-1}+K_{t} \tilde{y}_{t} \tag{25.11}
\end{equation*}
$$

Updated (a posteriori) estimate covariance

$$
\begin{equation*}
P_{t \mid t}=\left(I-K_{t} H_{t}\right) P_{t \mid t-1} \tag{25.12}
\end{equation*}
$$

Measurement post-fit residual

$$
\begin{equation*}
\tilde{y}_{t \mid t}=z_{t}-H_{t} \hat{x}_{t \mid t} \tag{25.13}
\end{equation*}
$$

## Chapter 26

## Linear and Logistic Regression

Figure 26.1: Linear Regression

Figure 26.2: B net of Fig 26.1 with new $\overrightarrow{\underline{Y}}$ node.
Estimators $\hat{y}$ for linear and logistic regression.

- Linear Regression: $y \in \mathbb{R}$. Note $\hat{y} \in \mathbb{R} .(x, \hat{y}(x))$ is the graph of a straight
line with y -intercept $b$ and slope $m$.

$$
\begin{equation*}
\hat{y}(x ; b, m)=b+m x \tag{26.1}
\end{equation*}
$$

- Logistic Regression: $y \in\{0,1\}$. Note $\hat{y} \in[0,1] .(x, \hat{y}(x))$ is the graph of a sigmoid. Often in literature, $b, m$ are replaced by $\beta_{0}, \beta_{1}$.

$$
\begin{equation*}
\hat{y}(x ; b, m)=\operatorname{sig}(b+m x) \tag{26.2}
\end{equation*}
$$

Define

$$
\begin{equation*}
V(b, m)=\sum_{x, y} P(x, y)|y-\hat{y}(x ; b, m)|^{2} \tag{26.3}
\end{equation*}
$$

We want to minimize $V(b, m)$ (called a cost or loss function) wrt $b$ and $m$.
Node TPMs of B net of Fig 26.1 given next in blue.

$$
\begin{equation*}
P(b, m)=\text { given } \tag{26.4}
\end{equation*}
$$

The first time it is used, $(b, m)$ is arbitrary. After the first time, it is determined by previous stage.

Let

$$
\begin{gather*}
P_{\underline{x}, \underline{y}}(x, y)=\frac{1}{n \operatorname{sam}(\vec{x})} \sum_{\sigma} \mathbb{1}(x=x[\sigma], y=y[\sigma]) .  \tag{26.5}\\
P(\vec{x})=\prod_{\sigma} P(x[\sigma])  \tag{26.6}\\
P(\vec{y} \mid \vec{x})=\prod_{\sigma} P(y[\sigma] \mid x[\sigma])  \tag{26.7}\\
P(\overrightarrow{\hat{y}} \mid \vec{x}, b, m)=\prod_{\sigma} \delta(\hat{y}[\sigma], \hat{y}(x[\sigma], b, m))  \tag{26.8}\\
P(V \mid \overrightarrow{\hat{y}}, \vec{y})=\delta\left(V, \frac{1}{n s a m(\vec{x})} \sum_{\sigma}|y[\sigma]-\hat{y}[\sigma]|^{2}\right) \tag{26.9}
\end{gather*}
$$

Let $\eta_{b}, \eta_{m}>0$. For $x=b, m$, if $x^{\prime}-x=\Delta x=-\eta \frac{\partial V}{\partial x}$, then $\Delta V \approx \frac{-1}{\eta}(\Delta x)^{2} \leq 0$ for $\eta>0$. This is called "gradient descent".

$$
\begin{gather*}
P\left(b^{\prime} \mid V, b\right)=\delta\left(b^{\prime}, b-\eta_{b} \partial_{b} V\right)  \tag{26.10}\\
P\left(m^{\prime} \mid V, m\right)=\delta\left(m^{\prime}, m-\eta_{m} \partial_{m} V\right) \tag{26.11}
\end{gather*}
$$

### 26.1 Generalization to $x$ with multiple components (features)

Suppose that for each sample $\sigma$, instead of $x[\sigma]$ being a scalar, it has $n$ components called features:

$$
\begin{equation*}
x[\sigma]=\left(x_{0}[\sigma], x_{1}[\sigma], x_{2}[\sigma], \ldots x_{n-1}[\sigma]\right) . \tag{26.12}
\end{equation*}
$$

Slope $m$ is replaced by weights

$$
\begin{equation*}
w=\left(w_{0}, w_{1}, w_{3}, \ldots, w_{n-1}\right), \tag{26.13}
\end{equation*}
$$

and the product of 2 scalars $m x[\sigma]$ is replaced by the inner vector product $w^{T} x[\sigma]$.

### 26.2 Alternative $V(b, m)$ for logistic regression

For logistic regression, since $y[\sigma] \in\{0,1\}$ and $\hat{y}[\sigma] \in[0,1]$ are both in the interval $[0,1]$, they can be interpreted as probabilities. Define probability distributions $p[\sigma](x)$ and $\hat{p}[\sigma](x)$ for $x \in\{0,1\}$ by

$$
\begin{array}{ll}
p[\sigma](1)=y[\sigma], & p[\sigma](0)=1-y[\sigma] \\
\hat{p}[\sigma](1)=\hat{y}[\sigma], & \hat{p}[\sigma](0)=1-\hat{y}[\sigma] \tag{26.15}
\end{array}
$$

Then for logistic regression, the following 2 cost functions $V(b, m)$ can be used as alternatives to the cost function Eq. (26.3) previously given.

$$
\begin{equation*}
V(b, m)=\frac{1}{n s a m(\vec{x})} \sum_{\sigma} D_{K L}(p[\sigma] \| \hat{p}[\sigma]) \tag{26.16}
\end{equation*}
$$

and

$$
\begin{align*}
V(b, m) & =\frac{1}{n \operatorname{sam}(\vec{x})} \sum_{\sigma} C E(p[\sigma] \rightarrow \hat{p}[\sigma])  \tag{26.17}\\
& =\frac{-1}{n \operatorname{sam}(\vec{x})} \sum_{\sigma}\{y[\sigma] \ln \hat{y}[\sigma]+(1-y[\sigma]) \ln (1-\hat{y}[\sigma])\}  \tag{26.18}\\
& =\frac{-1}{n \operatorname{sam}(\vec{x})} \sum_{\sigma} \ln \left\{\hat{y}[\sigma]^{y[\sigma]}(1-\hat{y}[\sigma])^{(1-y[\sigma])}\right\}  \tag{26.19}\\
& =\frac{-1}{n \operatorname{sam}(\vec{x})} \sum_{\sigma} \ln P(\underline{Y}=y[\sigma] \mid \hat{y}=\hat{y}[\sigma])  \tag{26.20}\\
& =-\sum_{x, y} P(x, y) \ln P(\underline{Y}=y \mid \hat{y}=\hat{y}(x, b, m)) \tag{26.21}
\end{align*}
$$

Above, we used

$$
\begin{equation*}
P(\underline{Y}=Y \mid \hat{y})=\hat{y}^{Y}[1-\hat{y}]^{1-Y} \tag{26.22}
\end{equation*}
$$

for $Y \in S_{\underline{Y}}=\{0,1\}$. (Bernoulli distribution).
There is no node corresponding to $\underline{Y}$ in the B net of Fig 26.1. Fig 26.2 shows a new B net that has a new node called $\vec{Y}$ compared to the B net of Fig 26.1. One defines the TPMs for all nodes of Fig. 26.2 except $\underline{\vec{Y}}$ and $\underline{V}$ the same as for Fig 26.1 . For $\underline{\vec{Y}}$ and $\underline{V}$, one defines

$$
\begin{align*}
& P(Y[\sigma] \mid \overrightarrow{\hat{y}})=P(\underline{Y}=Y[\sigma] \mid \hat{y}[\sigma])  \tag{26.23}\\
& P(V \mid \vec{Y}, \vec{y})=\delta\left(V, \frac{-1}{n \operatorname{sam}(\vec{x})} \ln \mathcal{L}\right), \tag{26.24}
\end{align*}
$$

where $\mathcal{L}=\prod_{\sigma} P(\underline{Y}=y[\sigma] \mid \hat{y}[\sigma])=$ likelihood.

## Chapter 27

## Linear Deterministic Bnets with External Noise

In this chapter, we will consider bnets which were referred to, prior to the invention of bnets, as: Sewall Wright's Path Analysis (PA) and linear Structural Equations Models (SEM). Judea Pearl in his books calls them linear Structural Causal Models (SCM), because they are very convenient for doing causal analysis. We will refer to them as linear Deterministic with External Noise (LDEN) diagrams. This chapter is devoted to LDEN diagrams, except that we will say a few words about non-linear DEN diagrams at the end.

A DEN diagram is a special kind of bnet. To build a DEN diagram, start with a deterministic bnet $G$. The deterministic nodes of $G$ are called the endogenous (internal) variables. Now make a bigger bnet $\bar{G}$ called a DEN diagram by adding to each node $\underline{a}$ of $G$ a non-deterministic root node $\underline{u}_{\underline{a}}$ pointing into $\underline{a}$ only. The nodes $\underline{u}_{\underline{a}}$ are called the exogenous (external) variables. The exogenous variables make their children noisy. They are assumed to be unobserved and their TPMs are prior probability distributions. Since they are root nodes, they are mutually independent. When we draw a DEN diagram, we will never draw the exogenous nodes, leaving them implicit.

A linear DEN diagram (LDEN) is a DEN diagram whose deterministic nodes have a TPM that is a linear function of the states of the parent nodes.

### 27.1 Example of LDEN diagram

The TPMs, printed in blue, for the nodes of the LDEN diagram Fig 27.1, are as follows.

$$
\begin{equation*}
P\left(y \mid w, z, u_{\underline{y}}\right)=\mathbb{1}\left(y=\epsilon w+\delta z+u_{\underline{y}}\right) \tag{27.1}
\end{equation*}
$$

Figure 27.1: Example of a LDEN diagram wherein $\underline{x}$ splits into two nodes $\underline{z}$ and $\underline{w}$, then merges into node $\underline{y}$. There is also an arrow $\underline{z} \rightarrow \underline{w}$. Exogenous nodes are not shown. The Greek letters represent real numbers.

$$
\begin{gather*}
P\left(w \mid x, z, u_{\underline{w}}\right)=\mathbb{1}\left(w=\beta x+\gamma z+u_{\underline{w}}\right)  \tag{27.2}\\
P\left(z \mid x, u_{\underline{z}}\right)=\mathbb{1}\left(z=\alpha x+u_{\underline{z}}\right)  \tag{27.3}\\
P\left(x \mid u_{\underline{x}}\right)=\mathbb{1}\left(x=u_{\underline{x}}\right) \tag{27.4}
\end{gather*}
$$

Hence,

$$
\begin{align*}
y & =\epsilon w+\delta z+u_{\underline{y}}  \tag{27.5}\\
& =\epsilon\left(\beta x+\gamma z+u_{\underline{w}}\right)+\delta z+u_{\underline{y}}  \tag{27.6}\\
& =(\epsilon \gamma+\delta) z+\epsilon \beta x+\epsilon u_{\underline{w}}+u_{\underline{y}}  \tag{27.7}\\
& =(\epsilon \gamma+\delta) z+\epsilon \beta u_{\underline{x}}+\epsilon u_{\underline{w}}+u_{\underline{y}} . \tag{27.8}
\end{align*}
$$

Therefore

$$
\begin{equation*}
\left(\frac{\partial y}{\partial z}\right)_{u .-u_{\underline{z}}}=\epsilon \gamma+\delta \tag{27.9}
\end{equation*}
$$

where the partial derivative holds fixed all exogenous variables except $u_{\underline{z}}$. Note that this partial derivative is a sum of terms, and that each of those terms represents a different directed path from $\underline{z}$ to $\underline{y}(\underline{z})$. This is a general property of LDEN diagrams.

### 27.2 Fully Connected LDEN diagrams

The bnets that will be considered in this section will all be fully connected. Fully connected bnets are defined in Chapter Definition of a Bayesian Network. This section uses the notation $\langle\underline{x}, \underline{y}\rangle$ for the covariance of any two random variables $\underline{x}, \underline{y}$.

This $\langle\underline{x}, \underline{y}\rangle$ notation is defined in the Notational Conventions Chapter Notational Conventions and Preliminaries.

Consider a LDEN diagram with deterministic nodes $\underline{x} .=\left(\underline{x}_{k}\right)_{k=0,1, \ldots n x-1}$ and corresponding exogenous nodes $\underline{u}$. $=\left(\underline{u}_{k}\right)_{k=0,1, \ldots n x-1}$. Assume $\left\langle\underline{u}_{i}, \underline{u}_{j}\right\rangle=0$ if $i \neq j$. The strength of each connection $\underline{x}_{i} \rightarrow \underline{x}_{j}$ of the LDEN diagram is measured by a structural coefficient $\alpha_{j \mid i} \in \mathbb{R}$. Some of the $\alpha_{j \mid i}$ may be zero, in which case the corresponding arrow $i \rightarrow j$ would not be drawn.

### 27.2.1 Fully connected LDEN diagram with $n x=2$

Figure 27.2: Fully connected LDEN diagram with two $\underline{x}_{j}$ nodes (exogenous nodes $\underline{u}_{j}$ not shown).

Consider the LDEN diagram of Fig 27.2. This diagram represents the following structural equations:

$$
\begin{align*}
& \underline{x}_{0}=\underline{u}_{0}  \tag{27.10a}\\
& \underline{x}_{1}=\alpha_{1 \mid 0} \underline{x}_{0}+\underline{u}_{1} . \tag{27.10b}
\end{align*}
$$

Eqs 27.10 constitute a system of 2 linear equations in 2 unknowns (the $\underline{x}$ 's) so we can solve for the $\underline{x}$ 's in terms of the $\alpha$ 's and $\underline{u}$ 's.

Note also that

$$
\begin{equation*}
\left\langle\underline{x}_{1}, \underline{x}_{0}\right\rangle=\alpha_{1 \mid 0}\left\langle\underline{x}_{0}, \underline{x}_{0}\right\rangle . \tag{27.11}
\end{equation*}
$$

Thus, $\alpha_{1 \mid 0}$ can be estimated from the covariances $\left\langle\underline{x}_{i}, \underline{x}_{j}\right\rangle$.

### 27.2.2 Fully connected LDEN diagram with $n x=3$

Figure 27.3: Fully connected LDEN diagram with three $\underline{x}_{j}$ nodes (exogenous nodes $\underline{u}_{j}$ not shown).

Consider the LDEN diagram of Fig.27.3. This diagram represents the following structural equations:

$$
\begin{align*}
& \underline{x}_{0}=\underline{u}_{0}  \tag{27.12a}\\
& \underline{x}_{1}=\alpha_{1 \mid 0} \underline{x}_{0}+\underline{u}_{1}  \tag{27.12b}\\
& \underline{x}_{2}=\alpha_{2 \mid 0} \underline{x}_{0}+\alpha_{2 \mid 1} \underline{x}_{1}+\underline{u}_{2} . \tag{27.12c}
\end{align*}
$$

Eqs 27.12 constitute a system of 3 linear equations in 3 unknowns (the $\underline{x}$ 's) so we can solve for the $\underline{x}$ 's in terms of the $\alpha$ 's and $\underline{u}$ 's.

Note also that

$$
\begin{align*}
\left\langle\underline{x}_{1}, \underline{x}_{0}\right\rangle & =\alpha_{1 \mid 0}\left\langle\underline{x}_{0}, \underline{x}_{0}\right\rangle  \tag{27.13a}\\
\left\langle\underline{x}_{2}, \underline{x}_{0}\right\rangle & =\alpha_{2 \mid 0}\left\langle\underline{x}_{0}, \underline{x}_{0}\right\rangle+\alpha_{2 \mid 1}\left\langle\underline{x}_{1}, \underline{x}_{0}\right\rangle  \tag{27.13b}\\
\left\langle\underline{x}_{2}, \underline{x}_{1}\right\rangle & =\alpha_{2 \mid 0}\left\langle\underline{x}_{0}, \underline{x}_{1}\right\rangle+\alpha_{2 \mid 1}\left\langle\underline{x}_{1}, \underline{x}_{1}\right\rangle \tag{27.13c}
\end{align*}
$$

Eqs 27.13 constitute a system of 3 linear equations in 3 unknowns (the $\alpha$ 's) so we can solve solve for the $\alpha$ 's in terms of covariances $\left\langle\underline{x}_{i}, \underline{x}_{j}\right\rangle$. This gives an estimate for the $\alpha$ 's.

### 27.2.3 Fully connected LDEN diagram with arbitrary $n x$

Let $\underline{x}$. $=\left(x_{i}\right)_{i=0,1, \ldots, n x-1}$ and $\underline{x}_{<i}=\left(x_{k}\right)_{k=0,1, \ldots, i-1}$. Consider a fully connected LDEN diagram with deterministic nodes labeled $\underline{x}_{i}$. The $\underline{x}_{i}$ labels are assumed to be in topological order (i.e., the parents of node $\underline{x}_{i}$ are $\underline{x}_{<i}$ ). Let the TPMs, printed in blue, for the nodes $\underline{x}$. of the LDEN diagram, be

$$
\begin{equation*}
P\left(x_{i} \mid x_{<i}, u_{i}\right)=\mathbb{1}\left(x_{i}=\sum_{k<i} \alpha_{i \mid k} x_{k}+u_{i}\right), \tag{27.14}
\end{equation*}
$$

for some parameters $\alpha_{i \mid k} \in \mathbb{R}$. The exogenous nodes $\underline{u}$. are assumed to be independent so

$$
\begin{equation*}
P(u .)=\prod_{i} P\left(u_{i}\right) \tag{27.15}
\end{equation*}
$$

and

$$
\begin{equation*}
\left\langle\underline{u}_{i}, \underline{u}_{j}\right\rangle=0 \text { if } i \neq j . \tag{27.16}
\end{equation*}
$$

Note that

$$
\begin{align*}
P(x .) & =\sum_{u .} P(u .) \prod_{i} P\left(x_{i} \mid x_{<i}, u_{i}\right)  \tag{27.17}\\
& =E_{\underline{u}}\left[\prod_{i} P\left(x_{i} \mid x_{<i}, u_{i}\right)\right] . \tag{27.18}
\end{align*}
$$

In terms of random variables, this system is described by the following structural equations:

$$
\begin{equation*}
\underline{x}_{i}=\sum_{k<i} \alpha_{i \mid k} \underline{x}_{k}+\underline{u}_{i} . \tag{27.19}
\end{equation*}
$$

The structural equations can be written in matrix form as follows. Define a strictly lower triangular matrix $A$ with the connection strengths $\alpha_{i \mid k} \in \mathbb{R}$ as entries. For example, for $n x=4$,

$$
A=\left[\begin{array}{cccc}
0 & 0 & 0 & 0  \tag{27.20}\\
\alpha_{1 \mid 0} & 0 & 0 & 0 \\
\alpha_{2 \mid 0} & \alpha_{2 \mid 1} & 0 & 0 \\
\alpha_{3 \mid 0} & \alpha_{3 \mid 1} & \alpha_{3 \mid 2} & 0
\end{array}\right]
$$

If we now represent the multinodes $\underline{x}$. and $\underline{u}$. as column vectors $\underline{x}$ and $\underline{u}$, we get

$$
\begin{equation*}
\underline{x}=A \underline{x}+\underline{u} . \tag{27.21}
\end{equation*}
$$

Note that

$$
\begin{equation*}
\underline{x}=(1-A)^{-1} \underline{u} . \tag{27.22}
\end{equation*}
$$

Therefore,

$$
\begin{equation*}
\underline{x}_{i}=f_{i}\left(\underline{u}_{\leq i}\right) . \tag{27.23}
\end{equation*}
$$

Therefore, if $i>j$,

$$
\begin{equation*}
\left\langle\underline{u}_{i}, \underline{x}_{j}\right\rangle=\left\langle\underline{u}_{i}, f_{j}\left(\underline{u}_{\leq j}\right)\right\rangle=0 . \tag{27.24}
\end{equation*}
$$

Thus, if $i>j$,

$$
\begin{align*}
\left\langle\underline{x}_{i}, \underline{x}_{j}\right\rangle & =\sum_{k<i} \alpha_{i \mid k}\left\langle\underline{x}_{k}, \underline{x}_{j}\right\rangle+\left\langle\underline{u}_{i}, \underline{x}_{j}\right\rangle  \tag{27.25}\\
& =\sum_{k<i} \alpha_{i \mid k}\left\langle\underline{x}_{k}, \underline{x}_{j}\right\rangle . \tag{27.26}
\end{align*}
$$

In matrix notation, Eq. 27.26 becomes

$$
\begin{equation*}
\left\langle\underline{x}, \underline{x}^{T}\right\rangle_{L}=A\left[\left\langle\underline{x}, \underline{x}^{T}\right\rangle_{L}+\left\langle\underline{x}, \underline{x}^{T}\right\rangle_{D}\right] \tag{27.27}
\end{equation*}
$$

where we are using $\left\langle\underline{x}, \underline{x}^{T}\right\rangle_{i, j}=\left\langle\underline{x}_{i}, \underline{x}_{j}\right\rangle$ and denoting the strictly lower triangular part and diagonal part of a matrix $M$ by $M_{L}$ and $M_{D}$. Thus,

$$
\begin{equation*}
A=\left\langle\underline{x}, \underline{x}^{T}\right\rangle_{L}\left[\left\langle\underline{x}, \underline{x}^{T}\right\rangle_{L}+\left\langle\underline{x}, \underline{x}^{T}\right\rangle_{D}\right]^{-1} \tag{27.28}
\end{equation*}
$$

This gives an estimate for the $\alpha$ 's in terms of the covariances $\left\langle\underline{x}_{i}, \underline{x}_{j}\right\rangle$.

### 27.3 Non-linear DEN diagrams

This chapter is dedicated to linear DEN diagrams. This implicitly assumes that the deterministic nodes $\underline{x}$. of the DEN diagram have an interval of real values as their possible states. A trivial but very useful generalization of linear DEN diagrams is to replace Eq. 27.14 ) for the TPMs of the deterministic nodes of the diagram by

$$
\begin{equation*}
P\left(x_{i} \mid x_{<i}, u_{i}\right)=\mathbb{1}\left(x_{i}=f_{i}\left(x_{<i}, u_{i}\right)\right), \tag{27.29}
\end{equation*}
$$

with structural equations

$$
\begin{equation*}
\underline{x}_{i}=f_{i}\left(\underline{x}_{<i}, \underline{u}_{i}\right), \tag{27.30}
\end{equation*}
$$

for $i=0,1, \ldots, n x-1$. Here the $f_{i}$ are possibly non-linear functions that depend the states $x_{<i}$ and $u_{i}$ of nodes $\underline{x}_{<i}$ and $\underline{u}_{i}$. If a node $\underline{x}_{i}$ has no arrows entering it (i.e., is a root node), then

$$
\begin{equation*}
P\left(x_{i} \mid x_{<i}, u_{i}\right)=P\left(x_{i}\right)=\delta\left(x_{i}, a\right) \tag{27.31}
\end{equation*}
$$

and

$$
\begin{equation*}
\underline{x}_{i}=a \tag{27.32}
\end{equation*}
$$

for some $a \in S_{\underline{x}_{i}}$.
With this generalization, we can make any $f_{i}()$ represent a continuous probability distribution such as a Gaussian, or a discrete-valued Boolean function such as an OR gate.

Eqs. 27.29 ) and $(27.30)$ are the TPMs and structural equations for a fully connected, non-linear DEN diagram. For a non-fully connected diagram,

- replace the multinode $x_{<i}$ by a subset of itself, in Eqs. 27.29) and 27.30), and
- delete the corresponding arrows from the graph.

## Chapter 28

## Markov Blankets

This chapter is based on the Wikipedia article, Ref. [66]. Markov blankets and Markov boundaries of bnets were apparently invented by Judea Pearl. His 1988 book Ref. [25], instead of a research paper, is usually given as the original reference.

Figure 28.1: In a bnet, the minimal Markov blanket, aka Markov boundary, of node $\underline{a}$.

We will treat vectors of random variables as if they were sets when using the $\in, \subset$ and - operations. For example, if $\underline{x}=\left(\underline{x}_{0}, \underline{x}_{1}, \underline{x}_{2}, \underline{x}_{3}\right)$ and $\underline{b}=\left(\underline{x}_{1}, \underline{x}_{2}\right)$, then $\underline{x}_{1} \in \underline{b} \subset \underline{x}$ and $\underline{x}-\underline{b}=\left(\underline{x}_{0}, \underline{x}_{3}\right)$.

Below, $H(\underline{a}: \underline{b} \mid \underline{c})$ denotes the conditional mutual information of random variables $\underline{a}$ and $\underline{b}$ conditioned on random variable $\underline{c}$. $H(\underline{a}: \underline{b} \mid \underline{c})$ is used in Shannon Information Theory, where it is defined by

$$
\begin{equation*}
H(\underline{a}: \underline{b} \mid \underline{c})=\sum_{a, b, c} P(a, b, c) \ln \frac{P(a, b \mid c)}{P(a \mid c) P(b \mid c)} . \tag{28.1}
\end{equation*}
$$

$H(\underline{a}: \underline{b} \mid \underline{c})=0$ iff $\underline{a}$ and $\underline{b}$ are independent (uncorrelated) when $\underline{c}$ is held fixed.

Suppose $\underline{a} \in \underline{X}, \underline{B} \subset \underline{X}$, but $\underline{a} \notin \underline{B}$. Then $\underline{B}$ is a Markov blanket of $\underline{a}$ if

$$
\begin{equation*}
H(\underline{a}: \underline{X}-\underline{a} \mid \underline{B})=0 . \tag{28.2}
\end{equation*}
$$

In other words, one may assume that $\underline{a}$ depends on $\underline{B}$ only, and is independent of all random variables in $\underline{X}-(\underline{a} \cup \underline{B})$.

The minimal Markov blanket is called the Markov boundary.
In a bnet, the Markov boundary of a node $\underline{a}$, contains:

1. the parents of $\underline{a}$,
2. the children of $\underline{a}$,
3. the parents, other than $\underline{a}$, of the children of $\underline{a}$.

This is illustrated in Fig 28.1.

## Chapter 29

## Markov Chain Monte Carlo (MCMC)

Monte Carlo methods are methods for using random number generation to sample probability distributions. The subject of Monte Carlo methods has many branches, as you can see from its Wikipedia category list, Ref. 69]. MCMC (Markov Chain Monte Carlo) is just one of those branches, albeit a major one. Metropolis-Hastings (MH) sampling is a very important MCMC method. Gibbs sampling is a special case of MH sampling. This chapter covers both, MH and Gibbs sampling. It also covers a few other types of sampling.

Throughout this chapter, we use $P_{\underline{x}}: S_{\underline{x}} \rightarrow[0,1]$ to denote the target probability distribution that we wish to obtain samples from.

### 29.1 Inverse Cumulative Sampling

For more info about this topic and some original references, see Ref. [59].
This is one of the simplest methods for obtaining samples from a probability distribution $P_{x}$, but it requires knowledge of the inverse cumulative distribution of $P_{\underline{x}}$, which is often not available.

The cumulative distribution function is defined by:

$$
\begin{equation*}
C U M_{\underline{x}}(x)=P(\underline{x}<x)=\int_{x^{\prime}<x} d x^{\prime} P_{\underline{x}}\left(x^{\prime}\right) . \tag{29.1}
\end{equation*}
$$

Note that

$$
\begin{equation*}
P_{\underline{x}}(x)=\frac{d}{d x} C U M_{\underline{x}}(x) . \tag{29.2}
\end{equation*}
$$

For $t=0,1, \ldots, T-1$, let
$\underline{u}^{(t)} \in[0,1]=$ random variable, uniformly distributed over $[0,1]$.
$\underline{\vec{x}}^{(t)}=\left(\underline{x}^{(t)}[\sigma]\right)_{\sigma=0,1, \ldots, n \operatorname{sam}(t)-1}$ where $\underline{x}^{(t)}[\sigma] \in S_{\underline{x}}$ for all $\sigma$. Vector of samples collected up to time $t$.

Figure 29.1: bnet for Inverse Cumulative Sampling
The TPMs, printed in blue, for the nodes of bnet Fig 29.1, are:

$$
\begin{gather*}
P\left(u^{(t)}\right)=1  \tag{29.3}\\
P\left(\vec{x}^{(t)} \mid \vec{x}^{(t-1)}, u^{(t)}\right)=\delta\left(\quad \vec{x}^{(t)},\left[\vec{x}^{(t-1)}, C U M_{\underline{x}}^{-1}\left(u^{(t)}\right)\right]\right) \tag{29.4}
\end{gather*}
$$

## Motivation

Figure 29.2: Motivation for Inverse Cumulative Sampling.
See Fig 29.2 .
Note that if $\underline{u}$ is uniformly distributed over the interval $[0,1]$ and $a \in[0,1]$, then

$$
\begin{equation*}
P(\underline{u}<a)=a . \tag{29.5}
\end{equation*}
$$

Thus

$$
\begin{align*}
P\left(C U M_{\underline{x}}^{-1}(\underline{u})<x\right) & =P\left(\underline{u}<C U M_{\underline{x}}(x)\right)  \tag{29.6}\\
& =C U M_{\underline{x}}(x) . \tag{29.7}
\end{align*}
$$

Therefore,

$$
\begin{equation*}
d P\left(C U M_{\underline{x}}^{-1}(\underline{u})<x\right)=P_{\underline{x}}(x) d x . \tag{29.8}
\end{equation*}
$$

### 29.2 Rejection Sampling

For more info about this topic and some original references, see Ref. [78].
This method samples from a "candidates" probability distribution $P_{\underline{c}}: S_{\underline{x}} \rightarrow$ $[0,1]$, in cases where sampling directly from the target probability distribution $P_{\underline{x}}$ : $S_{\underline{x}} \rightarrow[0,1]$ is not possible.

Figure 29.3: bnet for Rejection Sampling
For $t=0,1, \ldots, T-1$, let
$\underline{u}^{(t)} \in[0,1]=$ random variable, uniformly distributed over $[0,1]$.
$\underline{a}^{(t)} \in\{0,1\}=$ accept candidate? (no $=0$, yes $=1$ )
$\underline{c}^{(t)} \in S_{\underline{x}}=$ sample that is a candidate for being accepted
$\underline{\vec{x}}^{(t)}=\left(\underline{x}^{(t)}[\sigma]\right)_{\sigma=0,1, \ldots, \text { nsam }(t)-1}$ where $\underline{x}^{(t)}[\sigma] \in S_{\underline{x}}$ for all $\sigma$. Vector of samples collected up to time $t$.

This algorithm requires a priori definition of a candidate probability distribution $P_{\underline{c}}: S_{\underline{x}} \rightarrow \mathbb{R}$ such that

$$
\begin{equation*}
P_{\underline{x}}(x)<\beta P_{\underline{\underline{c}}}(x) \tag{29.9}
\end{equation*}
$$

for all $x \in S_{\underline{x}}$, for some $\beta \in \mathbb{R}$.
The TPMs, printed in blue, for the nodes of bnet Fig.29.3, are:

$$
\begin{gather*}
P\left(u^{(t)}=u\right)=1  \tag{29.10}\\
P\left(\underline{c}^{(t)}=c\right)=P_{\underline{c}}(c)  \tag{29.11}\\
P\left(\underline{a}^{(t)}=a \mid \underline{c}^{(t)}=c, \underline{u}^{(t)}=u\right)= \begin{cases}\delta(a, 0) & \text { if } u \beta P_{\underline{c}}(c) \geq P_{\underline{x}}(c) \\
\delta(a, 1) & \text { if } u \beta P_{\underline{c}}(c)<P_{\underline{x}}(c)\end{cases}  \tag{29.12}\\
P\left(\vec{x}^{(t)} \mid \vec{x}^{(t-1)}, \underline{a}^{(t)}=a, \underline{c}^{(t)}=c\right)= \begin{cases}\delta\left(\vec{x}^{(t)}, \vec{x}^{(t-1)}\right) & \text { if } a=0 \\
\delta\left(\vec{x}^{(t)},\left[\vec{x}^{(t-1)}, c\right]\right) & \text { if } a=1\end{cases} \tag{29.13}
\end{gather*}
$$

This last equation is only defined for $t>0$. For $t=0$, the left hand side reduces to $P\left(\vec{x}^{(0)}\right)$ which must be specified a priori.

## Motivation

Figure 29.4: Motivation for Rejection Sampling.

See Fig 29.4 .

### 29.3 Metropolis-Hastings Sampling

For more info about this topic and some original references, see Refs. [1] and [67].
An advantage of this method is that it can sample unnormalized probability distributions (constant) $P_{\underline{x}}$ because it only uses ratios of $P_{\underline{x}}$ at two different points. Another advantage of this method is that it scales much better than other sampling methods as the number of dimensions of the sampled variable $\underline{x}$ increases.

This method produces samples that take a finite amount of time to reach steady state. The samples are also theoretically correlated instead of being i.i.d. as one desires. To mitigate for the steady state problem, one discards an initial set of samples (the "burn-in" period). To mitigate for the correlation problem, one calculates the autocorrelation between the samples and keeps only samples separated by a time interval after which the samples cease to be autocorrelated to a good approximation.

For $t=0,1, \ldots, T-1$, let
$\underline{u}^{(t)} \in[0,1]=$ random variable, uniformly distributed over $[0,1]$.
$\underline{a}^{(t)} \in\{0,1\}=$ accept candidate? (no=0, yes=1)
$\underline{c}^{(t)} \in S_{x}=$ sample that is a candidate for being accepted
$\underline{m}^{(t)} \in \bar{S}_{\underline{x}}=$ memory of last accepted sample
$\underline{\vec{x}}^{(t)}=\left(\underline{x}^{(t)}[\sigma]\right)_{\sigma=0,1, \ldots, n s a m(t)-1}$ where $\underline{x}^{(t)}[\sigma] \in S_{\underline{x}}$ for all $\sigma$. Vector of samples collected up to time $t$.

A proposal TPM $P_{\underline{c} \mid \underline{x}}: S_{\underline{x}}^{2} \rightarrow[0,1]$ must be specified a priori for this algorithm.

The TPMs, printed in blue, for the nodes of bnet Fig.29.5, are:

$$
\begin{equation*}
P\left(u^{(t)}=u\right)=1 \tag{29.14}
\end{equation*}
$$

Figure 29.5: bnet for Metropolis-Hastings Sampling

$$
\begin{gather*}
P\left(\underline{c}^{(t)}=c \mid \underline{m}^{(t)}=m\right)=P_{\underline{c} \mid \underline{x}}(c \mid m)  \tag{29.15}\\
P\left(\underline{a}^{(t)}=a \mid \underline{c}^{(t)}=c, \underline{u}^{(t)}=u, \underline{m}^{(t)}=m\right)= \begin{cases}\delta(a, 0) & \text { if } u \geq \alpha(c \mid m) \\
\delta(a, 1) & \text { if } u<\alpha(c \mid m)\end{cases} \tag{29.16}
\end{gather*}
$$

where the acceptance probability $\alpha$ is defined as

$$
\begin{equation*}
\alpha(c \mid m)=\min \left(1, \frac{P_{\underline{c \mid x}}(m \mid c) P_{\underline{x}}(c)}{P_{\underline{c} \mid \underline{x}}(c \mid m) P_{\underline{x}}(m)}\right) . \tag{29.17}
\end{equation*}
$$

Note that if the proposal distribution is symmetric, then

$$
\begin{gather*}
\alpha(c \mid m)=\min \left(1, \frac{P_{\underline{x}}(c)}{P_{\underline{x}}(m)}\right) .  \tag{29.18}\\
P\left(\vec{x}^{(t)} \mid \vec{x}^{(t-1)}, \underline{a}^{(t)}=a, \underline{c}^{(t)}=c\right)= \begin{cases}\delta\left(\vec{x}^{(t)}, \vec{x}^{(t-1)}\right) & \text { if } a=0 \\
\delta\left(\vec{x}^{(t)},\left[\vec{x}^{(t-1)}, c\right]\right) & \text { if } a=1\end{cases} \tag{29.19}
\end{gather*}
$$

This last equation is only defined for $t>0$. For $t=0$, the left hand side reduces to $P\left(\vec{x}^{(0)}\right)$ which must be specified a priori.

$$
\begin{equation*}
P\left(\underline{m}^{(t)}=m \mid \vec{x}^{(t)}\right)=\delta\left(m, \text { last component of } \vec{x}^{(t)}\right) . \tag{29.20}
\end{equation*}
$$

This last equation is only defined for $t>0$. For $t=0$, the left hand side reduces to $P\left(\underline{m}^{(0)}=m\right)$ which must be specified a priori.

## Motivation

See Fig 29.6.

Figure 29.6: Motivation for Metropolis-Hastings Sampling.
Consider a time homogeneous (its TPM is the same for all times) Markov chain with TPM $P\left(x^{\prime} \mid x\right)=[T]_{x^{\prime}, x}$. Its stationary distribution, if it exists, is defined as

$$
\begin{equation*}
\pi=\lim _{n \rightarrow \infty} T^{n} \pi_{0} \tag{29.21}
\end{equation*}
$$

Suppose the prob distribution $P_{\underline{x}}(x)$ that we wish to sample from satisfies

$$
\begin{equation*}
P_{\underline{x}}(x)=\pi(x) . \tag{29.22}
\end{equation*}
$$

Reversibility (detailed balance): For all $x, x^{\prime} \in S_{\underline{x}}$,

$$
\begin{equation*}
P\left(x^{\prime} \mid x\right) \pi(x)=P\left(x \mid x^{\prime}\right) \pi\left(x^{\prime}\right) . \tag{29.23}
\end{equation*}
$$

Detailed balance is a sufficient (although not necessary) condition for a unique stationary prob distribution $\pi$ to exist $\prod^{1}$

Let

$$
\begin{equation*}
P\left(x^{\prime} \mid x\right)=P\left(\underline{a}=1 \mid x^{\prime}, x\right) P_{\underline{c} \mid \underline{\mid}}\left(x^{\prime} \mid x\right)+\delta\left(x, x^{\prime}\right) P(\underline{a}=0 \mid x), \tag{29.24}
\end{equation*}
$$

where

$$
\begin{equation*}
P(\underline{a}=0 \mid x)=\sum_{x^{\prime}} P\left(\underline{a}=0 \mid x^{\prime}, x\right) P_{\underline{c} \mid \underline{x}}\left(x^{\prime} \mid x\right) . \tag{29.25}
\end{equation*}
$$

Claim 21 If

$$
\begin{equation*}
P\left(\underline{a}=1 \mid x^{\prime}, x\right)=\alpha\left(x^{\prime} \mid x\right), \tag{29.26}
\end{equation*}
$$

[^13]then detailed balance is satisfied.
proof: Assume $x \neq x^{\prime}$.
\[

$$
\begin{align*}
P\left(x^{\prime} \mid x\right) P(x) & =P\left(\underline{a}=1 \mid x^{\prime}, x\right) P_{\underline{c} \mid \underline{x}}\left(x^{\prime} \mid x\right) P_{\underline{x}}(x)  \tag{29.27}\\
& =\min \left(1, \frac{P_{\underline{c} \mid \underline{x}}\left(x \mid x^{\prime}\right) P_{\underline{x}}\left(x^{\prime}\right)}{P_{\underline{c} \mid \underline{x}}\left(x^{\prime} \mid x\right) P_{\underline{x}}(x)}\right) P_{\underline{c} \mid \underline{x}}\left(x^{\prime} \mid x\right) P_{\underline{x}}(x)  \tag{29.28}\\
& =\min \left(P_{\underline{c \mid x}}\left(x^{\prime} \mid x\right) P_{\underline{x}}(x), P_{\underline{c \mid x}}\left(x \mid x^{\prime}\right) P_{\underline{x}}\left(x^{\prime}\right)\right)  \tag{29.29}\\
& =P\left(x \mid x^{\prime}\right) P\left(x^{\prime}\right) \tag{29.30}
\end{align*}
$$
\]

QED

### 29.4 Gibbs Sampling

For more info about this topic and some original references, see Ref. [55].
Gibbs sampling is a special case of Metropolis-Hastings sampling. Gibbs sampling is ideally suited for application to a bnet, because it is stated in terms of the conditional prob distributions of $N$ random variables, and conditional prob distributions are part of the definition of a bnet.

Consider a bnet with nodes $\underline{x}_{0}, \underline{x}_{1}, \ldots, \underline{x}_{N-1}$
Identify the random variable $\underline{x}=\left(\underline{x}_{0}, \underline{x}_{1}, \ldots, \underline{x}_{N-1}\right)$ with the random variable $\underline{x}$ used in Metropolis-Hastings sampling. For Gibbs sampling, we use the following proposal distribution:

$$
\begin{equation*}
P_{\underline{c} \underline{\mid}}(c \mid m)=\prod_{j=0}^{N-1} P\left(c_{j} \mid\left[m_{i}\right]_{i \neq j}\right) . \tag{29.31}
\end{equation*}
$$

Eq.(29.31) can be simplified using Markov Blankets (see Chapter 28) to the following:

$$
\begin{equation*}
P_{\underline{c} \mid \underline{x}}(c \mid m)=\prod_{j=0}^{N-1} P\left(c_{j} \mid\left[m_{i}: \forall i \ni \underline{x}_{i} \in M B\left(\underline{x}_{j}\right)\right]\right) \tag{29.32}
\end{equation*}
$$

where, for any node $\underline{a}$, we denote its Markov blanket by $M B(\underline{a})$.
An alternative proposal distribution that leads to much faster convergence is as follows. The idea is to make the components $c_{j}^{(t)}$ of candidate sample $c^{(t)}$ depend on the previous components $\left(c_{i}^{(t)}\right)_{i<j}$. See the bnet Fig 29.7. The TPM for the nodes of that bnet are

$$
\begin{equation*}
P\left(\underline{c}_{j}^{(t)}=c_{j} \mid\left(\underline{c}_{i}^{(t)}\right)_{i<j}=\left(c_{i}\right)_{i<j}, \underline{m}^{(t-1)}=m\right)=P\left(c_{j} \mid\left(c_{i}\right)_{i<j},\left(m_{i}\right)_{i>j}\right) \tag{29.33}
\end{equation*}
$$

Figure 29.7: In Gibbs sampling, the proposal distribution $P_{\underline{c \mid x}}$ can be defined by making the components $c_{j}^{(t)}$ of candidate sample $c^{(t)}$ depend on the previous components $\left(c_{i}^{(t)}\right)_{i<j}$.
for $j=0,1, \ldots, N-1$. This implies

$$
\begin{equation*}
P_{\underline{c} \mid \underline{x}}\left(\underline{c}^{(t)}=c \mid \underline{m}^{(t-1)}=m\right)=\prod_{j=0}^{N-1} P\left(c_{j} \mid\left(c_{i}\right)_{i<j},\left(m_{i}\right)_{i>j}\right) . \tag{29.34}
\end{equation*}
$$

As before, we can condition only on the Markov blanket of each node $\underline{x}_{j}$.
$P_{\underline{c} \mid \underline{x}}\left(\underline{c}^{(t)}=c \mid \underline{m}^{(t-1)}=m\right)=\prod_{j=0}^{N-1} P\left(c_{j} \mid\left(c_{i}\right)_{i<j},\left(m_{i}\right)_{i>j}\right.$, use only $c_{i}$ and $\left.m_{i} \ni \underline{x}_{i} \in M B\left(\underline{x}_{j}\right)\right)$.

### 29.5 Importance Sampling

For more info about this topic and some original references, see Ref. [57].
Suppose random variables $\underline{x}[\sigma] \in S_{\underline{x}}$ for $\sigma=0,1, \ldots, n s a m-1$ are i.i.d. with probability distribution $P_{\underline{x}}$. Then

$$
\begin{equation*}
E_{\underline{x}}[f(x)] \approx \frac{1}{n \operatorname{sam}} \sum_{\sigma=0}^{n s a m-1} f(x[\sigma]) \tag{29.36}
\end{equation*}
$$

for any $f: S_{\underline{x}} \rightarrow \mathbb{R}$. Sometimes, instead of using i.i.d. samples $\underline{x}[\sigma] \in S_{\underline{x}}$ where $\underline{x}[\sigma] \sim P_{\underline{x}}$, we wish to use i.i.d. samples $\underline{y}[\sigma] \in S_{\underline{x}}$ where $\underline{y}[\sigma] \sim P_{\underline{y}}$.

$$
\begin{align*}
E_{\underline{x}}[f(\underline{x})] & =\sum_{x} P_{\underline{x}}(x) f(x)  \tag{29.37}\\
& \left.=\sum_{x} P_{\underline{y}}(x)\right) \frac{P_{\underline{x}}(x)}{P_{\underline{y}}(x)} f(x)  \tag{29.38}\\
& =E_{\underline{y}}\left[\frac{P_{\underline{x}}(y)}{P_{\underline{y}}(y)} f(y)\right] \tag{29.39}
\end{align*}
$$

Sampling from $P_{\underline{y}}(y)$ instead of $P_{\underline{x}}(x)$ might reduce (or increase) variance for a particular $f: S_{\underline{x}} \rightarrow \mathbb{R}$.

$$
\begin{gather*}
\operatorname{Var}_{\underline{x}}[f(x)]=E_{\underline{x}}\left[(f(x))^{2}\right]-\left(E_{\underline{x}}[f(x)]\right)^{2}  \tag{29.40}\\
\operatorname{Var}_{\underline{\underline{y}}}\left[\frac{P_{\underline{x}}(y)}{P_{\underline{y}}(y)} f(y)\right]=E_{\underline{y}}\left[\left(\frac{P_{\underline{x}}(y)}{P_{\underline{y}}(y)} f(y)\right)^{2}\right]-\left(E_{\underline{y}}\left[\frac{P_{\underline{x}}(y)}{P_{\underline{y}}(y)} f(y)\right]\right)^{2}  \tag{29.41}\\
=E_{\underline{x}}\left[\frac{P_{\underline{x}}}{P_{\underline{y}}(x)}(f(x))^{2}\right]-\left(E_{\underline{x}}[f(x)]\right)^{2} \tag{29.42}
\end{gather*}
$$

## Chapter 30

## Markov Chains

A Markov Chain is simply a bnet with the graph structure of a chain. For example, Fig 30.1 shows a chain with $n=4$ nodes.

$$
\underline{x}_{0} \longrightarrow \underline{x}_{1} \longrightarrow \underline{x}_{2} \longrightarrow \underline{x}_{3}
$$

Figure 30.1: Markov chain with $n=4$ nodes.
Because of its graph structure, the TPM of each node only depends on the state of the previous node:

$$
\begin{equation*}
P\left(x_{t} \mid\left(x_{a}\right)_{a \neq t}\right)=P\left(x_{t} \mid x_{t-1}\right), \tag{30.1}
\end{equation*}
$$

where $\left(x_{a}\right)_{a \neq t}$ are all the nodes except $x_{t}$ itself and $t=1,2, \ldots, n-1$.
If there exists a single TPM $P_{\underline{x}_{1} \mid \underline{x}_{0}}$ such that

$$
\begin{equation*}
P\left(x_{t} \mid x_{t-1}\right)=P_{\underline{x}_{1} \mid \underline{x}_{0}}\left(x_{t} \mid x_{t-1}\right) \tag{30.2}
\end{equation*}
$$

for $t=1,2, \ldots, n-1$, then we say that the Markov chain is time homogeneous.
Claim 22 (Data Processing Inequality (DPI))
Consider a Markov chain $\underline{x}_{0} \rightarrow \underline{x}_{1} \cdots \rightarrow \underline{x}_{n-1}$. Suppose $0 \leq a<m<b \leq$ $n-1$. Then

$$
\begin{equation*}
H\left(\underline{x}_{a}: \underline{x}_{b}\right) \leq \min \left[H\left(\underline{x}_{a}: \underline{x}_{m}\right), H\left(\underline{x}_{m}: \underline{x}_{b}\right)\right] \tag{30.3}
\end{equation*}
$$

See Ref.[49] for references where the DPI is proven. This inequality confirms our intuitive expectations that the information transmitted (i.e., the mutual information(MI)) from $\underline{a}$ to $\underline{b}$ (or vice versa since MI is symmetric) is smaller or equal to the one transmitted from $\underline{a}$ to $\underline{m}$ or from $\underline{m}$ to $\underline{b}$ because $\underline{a}$ and $\underline{b}$ are "farther apart" and "some info can get lost during transmission through the mediator node $\underline{m}$ ".

## Chapter 31

## Message Passing (Belief Propagation)

Belief Propagation was first proposed in 1982 Ref. [24] by Judea Pearl to simplify the exact evaluation of the probability of one node conditioned on other nodes of a bnet (exact inference). It gives exact results for trees and polytrees (i.e. bnets with a single connected component and no loops). For bnets with loops, it gives approximate results (loopy belief propagation), and it has been generalized to the junction tree algorithm (see Chapter 24) which can do exact inference for general bnets with loops. The basic idea behind the junction tree algorithm is to eliminate loops by clustering them into single nodes.

In his book Ref.[25], Pearl explains two types of Message Passing (i.e., distributed computing in a bnet). In Chapter 4, he discusses one type of MP which he calls Belief Propagation (BP) or Belief Updating. In Chapter 5, he introduces a second type of MP which is he calls Belief Revision, but which I prefer to call Explanation Optimization (EO). This chapter will be devoted to BP only.

This chapter is mostly based on chapter 4 of Ref. [25] by Pearl. Refs.[42], and [18] were also helpful in writing this chapter.

### 31.1 Distributed Soldier Counting

Consider a group of soldiers marching single file. Fig 31.1 shows several methods by which a member of the group can obtain a count of the soldiers without breaking the line to do global operations. This can be done in a distributed fashion, with every soldier doing only local operations (i.e., each soldier can only send messages to either the soldier in front or the one in back). Such distributed soldier counting is a rudimentary type of BP . In the next section, we will generalize this BP for soldiers to BP for a Markov chain.

Figure 31.1: Distributed soldier counting (This example comes from Chapter 4 of Ref. 25 ]). Green dots indicate the beginning and red dots the end of a count. Only first soldier can calculate total count in (a). Only third soldier can calculate total count in (b,c). All soldiers can calculate the total count in (d,e). One starting point in (a,b,e). Two ends as starting points in (c,d).

### 31.2 Spring Systems

Figure 31.2: Spring system. Point masses connected by springs.
See Ref. 81 for an introduction to spring systems. Ideal springs between the point mass nodes would not be sufficient. One would have to add damping to the springs so as to reach an equilibrium. Time dependent forces (loads) pointing into or out of the page, applied to the point masses, would generate signals that would propagate like BP messages.

### 31.3 BP for Markov Chains

Figure 31.3: 3 node Markov chain $\underline{\epsilon}^{+} \leftarrow \underline{x} \leftarrow \underline{\epsilon}^{-}$. The $\pi$ messages (probability functions) travel downstream (i.e., they carry info in the direction of the graph arrows, towards the future) and are indicated by a dashed arrow or by a left double arrow $\Leftarrow$. The $\lambda$ messages (likelihood functions) travel upstream (i.e., they carry info opposite to direction of the graph arrows, towards the past) and are indicated by a dotted arrow or by a right double arrow $\Rightarrow . \underline{\epsilon}^{+}$stands for future evidence and $\underline{\epsilon}^{-}$for past evidence.

Consider the 3 node Markov chain $\underline{\epsilon}^{+} \leftarrow \underline{x} \leftarrow \underline{\epsilon}^{-}$shown in Fig 31.3. Defing ${ }^{1}$

$$
\begin{gather*}
\pi_{\underline{\epsilon}^{+} \Leftarrow \underline{x}}(x)=P\left(x \mid \epsilon^{-}\right) \text {(past of } \underline{x} \text { ) }  \tag{31.1}\\
\lambda_{\underline{\epsilon}^{+} \Rightarrow \underline{x}}(x)=P\left(\epsilon^{+} \mid x\right) \text { (future of } \underline{x} \text { ) }  \tag{31.2}\\
\pi_{\underline{x} \Leftarrow \underline{\epsilon}^{-}}\left(\epsilon^{-}\right)=P\left(\epsilon^{-}\right)=\delta\left(\epsilon^{-}, \epsilon_{0}^{-}\right) \text {(past of } \underline{\epsilon}^{-} \text {) }  \tag{31.3}\\
\left.\lambda_{\underline{x} \Rightarrow \underline{\epsilon}^{-}}\left(\epsilon^{-}\right)=P\left(\epsilon^{+} \mid \epsilon^{-}\right) \text {(future of } \underline{\epsilon}^{-}\right) . \tag{31.4}
\end{gather*}
$$

Furthermore, define the Belief BEL in $x$ to be

$$
\begin{equation*}
B E L_{\underline{x}}(x)=P(x \mid \epsilon), \tag{31.5}
\end{equation*}
$$

where

$$
\begin{equation*}
\underline{\epsilon}=\underline{\epsilon}^{+} \cup \underline{\epsilon}^{-} . \tag{31.6}
\end{equation*}
$$

It follows that

$$
\begin{align*}
B E L_{\underline{x}}(x) & =P\left(x \mid \epsilon^{+}, \epsilon^{-}\right)=  \tag{31.7}\\
& =\mathcal{N}(!x) P\left(\epsilon^{+}, x, \epsilon^{-}\right)  \tag{31.8}\\
& =\mathcal{N}(!x) P\left(\epsilon^{+} \mid x\right) P\left(x \mid \epsilon^{-}\right)  \tag{31.9}\\
& =\mathcal{N}(!x) \lambda_{\epsilon^{+}} \Rightarrow \underline{x}(x) \pi_{\epsilon^{+}} \underline{\epsilon}^{x}(x) \tag{31.10}
\end{align*}
$$

Note that Bayes rule would affirm that ${ }^{2}$

$$
\begin{equation*}
P\left(x \mid \epsilon^{+}\right)=\mathcal{N}(!x) \underbrace{P\left(\epsilon^{+} \mid x\right)}_{\underline{\underline{\epsilon}}^{+} \Rightarrow \underline{\underline{x}}} P(x) . \tag{31.11}
\end{equation*}
$$

Thus, Eq. 31.10 is like a 2-sided Janus Bayes rule.
Note that the $\pi$ messages and $\lambda$ messages propagate independently of each other, via the TPM $P\left(x \mid \epsilon^{-}\right)$:

$$
\begin{equation*}
\underbrace{\pi_{\epsilon^{+} \in \underline{x}}(x)}_{P\left(x \mid \epsilon_{0}^{-}\right)}=\sum_{\epsilon^{-}} P\left(x \mid \epsilon^{-}\right) \underbrace{\pi_{\underline{x} \epsilon \epsilon^{-}}\left(\epsilon^{-}\right)}_{\delta\left(\epsilon^{-}, \epsilon_{0}^{-}\right)} \tag{31.12a}
\end{equation*}
$$

[^14]\[

$$
\begin{equation*}
\underbrace{\lambda_{\underline{x} \Rightarrow \underline{\epsilon}^{-}}\left(\epsilon^{-}\right)}_{P\left(\epsilon^{+} \mid \epsilon^{-}\right)}=\sum_{x} P\left(x \mid \epsilon^{-}\right) \underbrace{\lambda_{\epsilon^{+}} \Rightarrow \underline{x}(x)}_{P\left(\epsilon^{+} \mid x\right)} \tag{31.12b}
\end{equation*}
$$

\]

Eqs.(31.12) suggest that we define an edge bnet for the $\pi$ and $\lambda$ messages (these messages live in the edges between the nodes $\underline{\epsilon}^{+}, \underline{x}, \underline{\epsilon}^{-}$). Such an edge bnet, shown in Fig. 31.4, is complementary to bnet for the nodes themselves. We will call it the BP 2-track bnet for the bnet Fig.31.3, because it has two "tracks", one for $\pi$ messages and another for $\lambda$ ones. The TPMs, shown in blue, for the nodes of bnet Fig 31.4, are as follows:

Figure 31.4: BP 2-track bnet for the bnet Fig 31.3.

$$
\begin{align*}
& P\left(\pi_{\underline{x} \Leftarrow \underline{\epsilon}^{-}}\right)=\prod_{\epsilon^{-}} \mathbb{1}\left(\pi_{\underline{x} \models \underline{\epsilon}^{-}}\left(\epsilon^{-}\right)=P\left(\epsilon^{-}\right)\right)  \tag{31.13}\\
& P\left(\pi_{\underline{\epsilon}^{+} \Leftarrow \underline{x}} \mid \pi_{\underline{x} \nleftarrow \underline{\epsilon}^{-}}\right)=\prod_{x} \mathbb{1}\left(\pi_{\underline{\epsilon}^{+} \Leftarrow \underline{x}}(x)=\sum_{\epsilon^{-}} P\left(x \mid \epsilon^{-}\right) \pi_{\underline{x} \Leftarrow \underline{\epsilon}^{-}}\left(\epsilon^{-}\right)\right)  \tag{31.14}\\
& P\left(B_{\underline{x}} \mid \pi_{\underline{\epsilon}+\Leftarrow \underline{x}}, \lambda_{\underline{\epsilon}+\Rightarrow \underline{x}}\right)=\prod_{x} \mathbb{1}\left(B_{\underline{x}}(x)=B E L_{\underline{x}}(x)\right)  \tag{31.15}\\
& P\left(\lambda_{\underline{\epsilon}^{+} \Rightarrow \underline{x}}\right)=\prod_{x} \mathbb{1}\left(\lambda_{\underline{\epsilon}^{+} \Rightarrow \underline{x}}(x)=P\left(\epsilon^{+} \mid x\right)\right)  \tag{31.16}\\
& P\left(\lambda_{\underline{x} \Rightarrow \underline{\epsilon}^{-}} \mid \lambda_{\underline{\epsilon}^{+} \Rightarrow \underline{x}}\right)=\prod_{\epsilon^{-}} \mathbb{1}\left(\lambda_{\underline{x} \Rightarrow \underline{\underline{t}}^{-}}\left(\epsilon^{-}\right)=\sum_{x} P\left(x \mid \epsilon^{-}\right) \lambda_{\underline{\epsilon}^{+} \Rightarrow \underline{x}}(x)\right) \tag{31.17}
\end{align*}
$$

Figure 31.5: 5 node Markov chain

So far in this section, we have considered Markov chains with 3 nodes. Before concluding our discussion of BP for Markov chains, let us consider BP for a slightly longer chain. Let us consider the 5 node Markov chain $\underline{\epsilon}^{+} \leftarrow \underline{b} \leftarrow \underline{x} \leftarrow \underline{a} \leftarrow \underline{\epsilon}^{-}$shown in Fig 31.5. We have already dealt with the end nodes of a Markov chain in the 3 node Markov chain example above, so in the 5 node case, let us focus on the internal (i.e., not at an end) node $\underline{x}$ and its neighbors $\underline{a}$ and $\underline{b}$. Define

$$
\begin{align*}
& \pi_{\underline{b} \leftarrow \underline{x}}(x)=P\left(x \mid \epsilon^{-}\right)(\text {past of } \underline{x}),  \tag{31.18}\\
& \lambda_{\underline{b} \Rightarrow \underline{x}}(x)=P\left(\epsilon^{+} \mid x\right)(\text { future of } \underline{x}),  \tag{31.19}\\
& \pi_{\underline{x} \Leftarrow \underline{a}}(a)=P\left(a \mid \epsilon^{-}\right)(\text {past of } \underline{a}) \tag{31.20}
\end{align*}
$$

and

$$
\begin{equation*}
\left.\lambda_{\underline{x} \Rightarrow \underline{a}}(a)=P\left(\epsilon^{+} \mid a\right) \text { (future of } \underline{a}\right) . \tag{31.21}
\end{equation*}
$$

Define the Belief BEL in $x$ to be

$$
\begin{equation*}
B E L_{\underline{x}}(x)=P(x \mid \epsilon), \tag{31.22}
\end{equation*}
$$

where

$$
\begin{equation*}
\underline{\epsilon}=\underline{\epsilon}^{+} \cup \underline{\epsilon}^{-} . \tag{31.23}
\end{equation*}
$$

Then

$$
\begin{align*}
B E L_{\underline{x}}(x) & =\mathcal{N}(!x) P\left(\epsilon^{+} \mid x\right) P\left(x \mid \epsilon^{-}\right)  \tag{31.24}\\
& =\mathcal{N}(!x) \lambda_{\underline{b}=\underline{x}}(x) \pi_{\underline{b}=\underline{x}}(x) . \tag{31.25}
\end{align*}
$$

In analogy with the case of BP for a 3 node Markov chain, we can define the bnet Fig. 31.6, which we refer to as the BP 2-track bnet for Fig.31.5. The TPMs, printed in blue, for the nodes of bnet Fig. 31.6, are as follows:

$$
\begin{equation*}
P\left(\pi_{\underline{b} \models \underline{x}} \mid \pi_{\underline{x} \Leftarrow \underline{a}}\right)=\prod_{x} \mathbb{1}\left(\pi_{\underline{b} \Leftarrow \underline{x}}(x)=\sum_{a} P(x \mid a) \pi_{\underline{x} \Leftarrow \underline{a}}(a)\right) \tag{31.26}
\end{equation*}
$$

Figure 31.6: BP 2-track bnet for the bnet Fig 31.5 .

$$
\begin{gather*}
P\left(B_{\underline{x}} \mid \pi_{\underline{b} \in \underline{x}}, \lambda_{\underline{b} \Rightarrow \underline{x}}\right)=\prod_{x} \mathbb{1}\left(B_{\underline{x}}(x)=B E L_{\underline{x}}(x)\right)  \tag{31.27}\\
P\left(\lambda_{\underline{x} \Rightarrow \underline{a}} \mid \lambda_{\underline{b} \Rightarrow \underline{x}}\right)=\prod_{a} \mathbb{1}\left(\lambda_{\underline{x} \Rightarrow \underline{a}}(a)=\sum_{x} P(x \mid a) \lambda_{\underline{b} \Rightarrow \underline{x}}(x)\right) \tag{31.28}
\end{gather*}
$$

Let us represent the Markov chain of Fig 31.5 by $\underline{x}_{n x-1} \leftarrow \ldots, \underline{x}_{2} \leftarrow \underline{x}_{1} \leftarrow \underline{x}_{0}$ where $n x=5$. For any node $\underline{x}_{i}$ with parent $\underline{p x}_{i}=\underline{x}_{i-1}$ and child $\underline{c x}_{i}=\underline{x}_{i+1}$, define the memory matrix $\mathcal{M}_{\underline{x}_{i}}$ for node $\underline{x}_{i}$ as

$$
\begin{equation*}
\mathcal{M}_{\underline{x}_{i}}=\left[\mathcal{M}_{\underline{x}_{i}}^{+}, \mathcal{M}_{\underline{\underline{x}}_{i}}^{-}\right], \tag{31.29}
\end{equation*}
$$

where $+=$ future, $-=$ past, and

Note that

$$
\begin{equation*}
\mathcal{M}_{\underline{\underline{x}}_{i}}^{-}=\mathcal{M}_{\underline{p x}}^{i} \tag{31.31}
\end{equation*}
$$

for all nodes $\underline{x}_{i}$. We will refer to Eqs. 31.31) as the memory overlap conditions.
We will also use a permuted version of the memory matrix

$$
\begin{equation*}
\mathcal{M}_{\underline{x}_{i}}^{\prime}=\left[\mathcal{M}_{\underline{x}_{i}}^{O U T}, \mathcal{M}_{\underline{x}_{i}}^{I N}\right], \tag{31.32}
\end{equation*}
$$

where

$$
\mathcal{M}_{\underline{\underline{x}}_{i}}^{O U T}=\left[\begin{array}{c}
\pi_{\underline{c x_{i}} \leftarrow \underline{x}_{i}}(\cdot)  \tag{31.33}\\
\lambda_{\underline{x}_{i} \Rightarrow \underline{\underline{p}}}(\cdot)
\end{array}\right], \quad \mathcal{M}_{\underline{x}_{i}}^{I N}=\left[\begin{array}{c}
\pi_{\underline{x}_{i} \leftarrow \underline{p x_{i}}}(\cdot) \\
\lambda_{\underline{c \underline{x}}}(\cdot) \underline{x}_{i}(\cdot)
\end{array}\right] .
$$

Unfortunately, 2-track bnets cannot be generalized in any obvious way from Markov chains to more complicated DAGs. An alternative to 2-track bnets that still

$$
\underline{\mathcal{M}}_{\underline{\epsilon}^{+}} \longleftarrow \underline{\mathcal{M}}_{\underline{b}} \longleftarrow \underline{\mathcal{M}}_{\underline{x}} \longleftarrow \underline{\mathcal{M}}_{\underline{a}} \longleftarrow \mathcal{M}_{\underline{\epsilon}^{-}}
$$

Figure 31.7: BP Memory Bnet for the bnet Fig 31.5 .
carries message info in its nodes, are memory bnets. An BP memory bnet is a bnet which takes each node of an original bnet and adds a local memory to it. More specifically, it keeps tha DAG but replaces each node $\underline{x}_{i}$ by a memory $\underline{\mathcal{M}}_{\underline{x}_{i}}$. Fig. 31.7 shows the memory bnet for the bnet Fig 31.5. The TPM, printed in blue, for the node $\underline{\mathcal{M}}_{\underline{x}}$ of the memory bnet Fig 31.7 , is as follows

$$
\begin{equation*}
P\left(\mathcal{M}_{\underline{x}_{i}} \mid \mathcal{M}_{\underline{n} \in n b\left(\underline{x}_{i}\right)}\right)=A B, \tag{31.34}
\end{equation*}
$$

where

$$
\begin{equation*}
A=\mathbb{1}\left(\mathcal{M}_{\underline{x}_{i}}^{-}=\mathcal{M}_{\underline{p} \underline{x}_{i}}^{+}\right), \tag{31.35}
\end{equation*}
$$

and

$$
\begin{equation*}
B=\mathbb{1}\left(\mathcal{M}_{\underline{x}_{i}}^{O U T}=\mathcal{C}\left(\mathcal{M}_{\underline{x}_{i}}^{I N}\right)\right) . \tag{31.36}
\end{equation*}
$$

The function $\mathcal{C}$, which we will call the BP local computation, maps $\mathcal{M}_{\underline{x}_{i}}^{I N}$ into $\mathcal{M}_{\underline{x}_{i}}^{O U T}$. More explicitly, $\mathcal{C}$ is defined so that

$$
\begin{equation*}
B=\underbrace{P\left(\pi_{\underline{b} \Leftarrow \underline{x}} \mid \pi_{\underline{x} \Leftarrow a}\right)}_{B_{\pi}} \underbrace{P\left(\lambda_{\underline{x} \Rightarrow \underline{a}} \mid \lambda_{\underline{b} \Rightarrow \underline{x}}\right)}_{B_{\pi}}, \tag{31.37}
\end{equation*}
$$

where $B_{\pi}$ and $B_{\lambda}$ are given by Eqs.(31.26) and (31.28), respectively.
The BP memory bnet Fig. 31.7 is a deterministic bnet. A deterministic bnet is basically just a coupled system of equations (CSE) for some unknowns $x_{i}$. A CSE per se does not include with it a method for solving for the $x_{i}$. Such methods are not unique. For example, for the distributed soldier counting problem, the various methods that we described for counting soldiers are just different methods for solving the same CSE. One can describe a method for solving a CSE using a dynamic bnet ${ }^{3}$ To solve the CSE represented by the memory bnet Fig 31.7, we will use the dynamic bnet Fig 31.8. Henceforth, we will refer to Fig 31.8 as an BP dynamic bnet for Fig 31.7.

Next, we will explain the meaning of Fig 31.8. Fig 31.8 is a step by step recipe (i.e., algorithm) for solving a SCE, where the unknowns are memory matrices. Each step encoded in Fig 31.8 corresponds to a specific message sending event, where the messages are sent along the edges of the Markov chain Fig.31.5. These message sending events are portrayed in chronological order in Fig.31.9. In that figure, $\pi$

[^15]

Figure 31.8: BP dynamic bnet for the bnet Fig 31.7 .

Figure 31.9: Steps encoded in the bnet Fig. 31.8. Note the similarity of this figure to Fig 31.1 (d) for soldier counting.
messages are indicated by dashed red arrows, and $\lambda$ messages by dotted red arrows. These steps, or message sending events, lead to an updating of the memory matrices that we are solving for. Each step propagates information between the memory nodes. In the usual Pearl BP algo, the evidence nodes initiate the BP chain of message passing events. These events continue until the memory matrices reach an equilibrium and the SCE is solved.

To use bnet Fig 31.8, we need to specify the initial conditions (i.e., the value of $\mathcal{M}_{\underline{x}_{i}}^{(0)}$ for all $i$ ). For that, one can use

$$
\begin{equation*}
\pi_{\underline{p} \underline{x}_{0} \leftarrow \underline{x}_{0}}^{(0)}=P\left(x_{0}\right), \tag{31.38}
\end{equation*}
$$

$$
\begin{equation*}
\lambda_{\underline{c x_{i}} \Rightarrow \underline{x}_{n x-1}}^{(0)}\left(x_{n x-1}\right)=\delta\left(x_{n x-1}, x_{n x-1}^{\prime}\right) . \tag{31.39}
\end{equation*}
$$

All other $\mathcal{M}_{\underline{x}_{i}}^{(0)}$ entries for all $i$ can be set to 1 .
The TPMs, printed in blue, for the nodes of Fig.31.8, can all be summarized by

$$
\begin{equation*}
P\left(\mathcal{M}_{\underline{x}_{i}}^{(t)} \mid \mathcal{M}_{\underline{n} \in n b\left(\underline{x}_{i}\right)}^{(t-1)}, \mathcal{M}_{\underline{x}_{i}}^{(t-1)}\right)=A B \tag{31.40}
\end{equation*}
$$

where

$$
A= \begin{cases}\mathbb{1}\left(\mathcal{M}_{\underline{x}_{i}}^{(t)-}=\mathcal{M}_{\underline{p x_{i}}}^{(t-1)+}\right) & \text { if input from }{\underline{p x_{i}}}_{i}  \tag{31.41}\\ \mathbb{1}\left(\mathcal{M}_{\underline{x}_{i}}^{(t)+}=\mathcal{M}_{\underline{c x_{i}}}^{(t-1)-}\right) & \text { if input from } \underline{c x}_{i}\end{cases}
$$

and

$$
\begin{equation*}
B=\mathbb{1}\left(\mathcal{M}_{\underline{x}_{i}}^{(t) O U T}=\mathcal{C}\left(\mathcal{M}_{\underline{x}_{i}}^{(t) I N}\right)\right) \tag{31.42}
\end{equation*}
$$

The function $\mathcal{C}$, which we will call the BP local computation, maps $\mathcal{M}_{x_{i}}^{(t) I N}$ into $\mathcal{M}_{\underline{x}_{i}}^{(t) O U T}$. More explicitly, $\mathcal{C}$ is defined so that

$$
\begin{equation*}
B=B_{\pi} B_{\lambda} \tag{31.43}
\end{equation*}
$$

where

$$
\begin{equation*}
B_{\pi}=\prod_{x} \mathbb{1}(\underbrace{\pi_{b b=x}^{(t)}(x)}_{O U T}=\sum_{a} P(x \mid a) \underbrace{\pi_{x \leftarrow a}^{(t)}(a)}_{I N}) \tag{31.44}
\end{equation*}
$$

and

$$
\begin{equation*}
B_{\lambda}=\prod_{a} \mathbb{1}(\underbrace{\lambda_{\text {x }}^{(t)}(a)}_{O U T}=\sum_{x} P(x \mid a) \underbrace{\lambda_{b=\underline{x}}^{(t)}(x)}_{I N}) \tag{31.45}
\end{equation*}
$$

The basic idea behind Eq. (31.42), which we will call the memory updating equation, is simple: the memory overlap conditions translate the information from time $t-1$ to $t$, and then the local computation translates $I N$ to $O U T$ at fixed time $t$.

### 31.4 BP Algorithm for Polytrees

Consider Fig 31.10 , which illustrates a bnet node $\underline{x}$ receiving and sending messages to its neighbors. The $\pi$ messages (probability functions) travel downstream (i.e.,
they carry info in the direction of the graph arrows, towards the future) and are indicated by a dashed arrow or by a left double arrow $\Leftarrow$. The $\lambda$ messages (likelihood functions) travel upstream (i.e., they carry info opposite to direction of the graph arrows, towards the past) and are indicated by a dotted arrow or by a right double arrow $\Rightarrow$.

Note that argument $\arg$ of the $\pi(\arg )$ and $\lambda(\arg )$ functions is always the same as the letter in the subscript that is closest to the argument.

Note that in Fig 31.10, we indicate messages that travel "downstream" (resp., "upstream"), by arrows with dashed (resp., dotted) lines as shafts. Mnemonic: think of the shaft as a velocity vector field for the message. You travel faster when you swim downstream as opposed to upstream.
$p a(\underline{x})=$ parents of node $\underline{x}$
$\operatorname{ch}(\underline{x})=$ children of node $\underline{x}$
$n b(\underline{x})=p a(\underline{x}) \cup \operatorname{ch}(\underline{x})=$ neighbors of node $\underline{x}$

Figure 31.10: Node $\underline{x}$ receiving and sending messages to its neighbors. (neighbors= parents and children).

We define a memory matrix $\mathcal{M}_{\underline{x}}$ for node $\underline{x}$ as

$$
\begin{equation*}
\mathcal{M}_{\underline{x}}=\left[\mathcal{M}_{\underline{x}}^{+}, \mathcal{M}_{\underline{x}}^{-}\right], \tag{31.46}
\end{equation*}
$$

where $+=$ future,$-=$ past, and

$$
\begin{gather*}
\mathcal{M}_{\underline{x}}^{+}=\left[\begin{array}{ll}
\pi_{\underline{b} \Leftarrow \underline{x}}(\cdot) & \lambda_{\underline{b} \Rightarrow \underline{x}}(\cdot)
\end{array}\right]_{\underline{b} \in c h(\underline{x})}=\left[\mathcal{M}_{\underline{b}, \underline{x} \underline{b} \in c h(\underline{x})}^{+},\right.  \tag{31.47}\\
\mathcal{M}_{\underline{x}}^{-}=\left[\begin{array}{c}
\pi_{\underline{x} \in \underline{a}}(\cdot) \\
\lambda_{\underline{x}=\underline{a}}(\cdot)
\end{array}\right]_{\underline{a} \in p a(\underline{x})}=\left[\mathcal{M}_{\underline{x}, \underline{a}}^{-}\right]_{\underline{a} \in p a(\underline{x})} . \tag{31.48}
\end{gather*}
$$

Note that

$$
\begin{equation*}
\mathcal{M}_{\underline{x}, \underline{a}}^{-}=\mathcal{M}_{\underline{a}, \underline{x}}^{+} \tag{31.49}
\end{equation*}
$$

for every arrow $\underline{x} \leftarrow \underline{a}$. We will refer to Eqs. (31.49) as the memory overlap conditions.

We will also use a permuted version of the memory matrix

$$
\begin{equation*}
\mathcal{M}_{\underline{x}}^{\prime}=\left[\mathcal{M}_{\underline{x}}^{O U T}, \mathcal{M}_{\underline{x}}^{I N}\right], \tag{31.50}
\end{equation*}
$$

where

$$
\begin{gather*}
\mathcal{M}_{\underline{x}}^{O U T}=\binom{\left[\pi_{\underline{b} \in \underline{x}}(\cdot)\right]_{\underline{b \in c h(\underline{x})}}}{\left[\lambda_{\underline{x} \Rightarrow \underline{a}}(\cdot)\right]_{\underline{a} \in p a(\underline{x})},}=\left[\mathcal{M}_{\underline{x}, \underline{\underline{n}}}^{O U T}\right]_{\underline{n} \in n b(\underline{x})},  \tag{31.51}\\
\mathcal{M}_{\underline{x}}^{I N}=\binom{\left[\pi_{\underline{x} \Leftarrow \underline{a}}(\cdot)\right]_{\underline{a} \in p a(\underline{x})}}{\left[\lambda_{\underline{b} \Rightarrow \underline{x}}(\cdot)\right]_{\underline{b} \in c h(\underline{x})}}=\left[\mathcal{M}_{\underline{x}, \underline{n} \underline{n} \in n b(\underline{x})}^{I N}\right]_{\underline{n}} . \tag{31.52}
\end{gather*}
$$

For times $t=0,1, \ldots, T-1$, we calculate $\mathcal{M}_{\underline{x}}^{(t)}$ in two steps: first we calculate $\mathcal{M}_{\underline{x}}^{(t) I N}$ from earlier memories at time $t-1$, then we calculate $\mathcal{M}_{\underline{x}}^{(t) O U T}$ :

$\lambda_{\underline{x} \Rightarrow \underline{a}}$

$\pi_{\underline{b} \Leftarrow \underline{x}}$

Figure 31.11: Subgraph of a bnet showing two cases (RULE 1 and RULE 2) of message info flow. The yellow node is a gossip monger. It receives messages from all the green nodes, and then it relays a joint message to the red node. Union of green nodes and the red node $=$ full neighborhood of yellow node. There are two possible cases: the red node is either a parent or a child of the yellow one. As usual, we use arrows with dashed (resp., dotted) shafts for downstream (resp., upstream) messages. Blue boxes indicate Markov chain case.

An evidence node is a node whose TPM is a delta function set to a particular state of the node. We will assume, without loss of generality, that all evidence nodes are leaf nodes. If that is not the case, any evidence node $\underline{e}$ that is not a leaf node, can be given a new companion leaf node $\underline{l}$ connected to $\underline{e}$ by an arrow $\underline{l} \leftarrow \underline{e}$, and such that $\underline{l}$ has a delta function TPM.

1. Calculating $\mathcal{M}_{\underline{x}}^{(t) I N}$ from signals received from $\underline{n} \in n b(\underline{x})$, sent at earlier time $t-1$ :

Set

$$
\begin{equation*}
\left.\mathcal{M}_{\underline{x}, \underline{a}}^{(t)-}\right|_{\pi}=\left.\mathcal{M}_{\underline{a}, \underline{x}}^{(t-1)+}\right|_{\pi} \tag{31.53}
\end{equation*}
$$

for all $\underline{a} \in p a(\underline{x})$, and

$$
\begin{equation*}
\left.\mathcal{M}_{\underline{b}, \underline{x}}^{(t)+}\right|_{\lambda}=\left.\mathcal{M}_{\underline{x}, \underline{b}}^{(t-1)-}\right|_{\lambda}, \tag{31.54}
\end{equation*}
$$

for all $\underline{b} \in \operatorname{ch}(\underline{x})$. By $\left.X\right|_{\lambda}$ (resp., $\left.X\right|_{\pi}$ ) we mean the $\lambda$ (resp., $\pi$ ) component of $X$.
2. Calculating $\mathcal{M}_{\underline{x}}^{(t) O U T}$ from already calculated $\mathcal{M}_{\underline{x}}^{(t) I N}$ :

Let $\underline{a}^{n a}=\left(\underline{a}_{i}\right)_{i=0,1, \ldots, n a-1}$ denote the parents of $\underline{x}$ and $\underline{b}^{n b}=\left(\underline{b}_{i}\right)_{i=0,1, \ldots, n b-1}$ its children.
Define

$$
\begin{align*}
\pi_{\underline{x}}(x) & =\sum_{a^{n a}} P\left(x \mid a^{n a}\right) \prod_{i} \pi_{\underline{x} \not \underline{a}_{i}}\left(a_{i}\right)  \tag{31.55}\\
& =E_{\underline{a}^{n a}}\left[P\left(x \mid a^{n a}\right)\right] \tag{31.56}
\end{align*}
$$

(boundary case: if $\underline{x}$ is a root node, use $\pi_{\underline{x}}(x)=P(x)$.) and

$$
\begin{equation*}
\lambda_{\underline{x}}(x)=\prod_{i} \lambda_{\underline{b}_{i} \Rightarrow \underline{x}}(x) . \tag{31.57}
\end{equation*}
$$

(boundary case: if $\underline{x}$ is a leaf node, use $\lambda_{\underline{x}}(x)=1$.)

- RULE 1: (red parent)

From the $\lambda_{\underline{x} \Rightarrow \underline{a}}$ panel of Fig 31.11, we get

$$
\begin{align*}
\underbrace{\lambda_{\underline{x} \Rightarrow a_{i}}\left(a_{i}\right)}_{\text {OUT }} & =\mathcal{N}\left(!a_{i}\right) \sum_{x}[\underbrace{\lambda_{\underline{x}}(x)}_{I N} \sum_{\left(a_{k}\right)_{k \neq i}}(P\left(x \mid a^{n a}\right) \prod_{k \neq i} \underbrace{\pi_{x \in a_{k}}\left(a_{k}\right)}_{I N})]  \tag{31.58}\\
& =\mathcal{N}\left(!a_{i}\right) \sum_{x}\left[\lambda_{\underline{x}}(x) E_{\left(\underline{a}_{k}\right)_{k \neq i}}\left[P\left(x \mid a^{n a}\right)\right]\right]  \tag{31.59}\\
& =\mathcal{N}\left(!a_{i}\right) E_{\left(\underline{a}_{k}\right)_{k \neq i}} E_{\underline{x} \mid a^{n a}} \lambda_{\underline{x}}(x) \tag{31.60}
\end{align*}
$$

(boundary case: if $\underline{x}$ is a root node, use $\lambda_{\underline{x} \Rightarrow \underline{a}_{i}}\left(a_{i}\right)=\mathcal{N}\left(!a_{i}\right)$.)

## - RULE 2: (red child)

From the $\pi_{\underline{b} \in \underline{x}}$ panel of Fig, 31.11, we get

$$
\begin{equation*}
\underbrace{\pi_{b_{i} \in x}(x)}_{O U T}=\mathcal{N}(!x) \underbrace{\pi_{x}(x)}_{I N} \prod_{k \neq i} \underbrace{\lambda_{b_{k} \Rightarrow x}(x)}_{I N} \tag{31.61}
\end{equation*}
$$

(boundary case: if $\underline{x}$ is a leaf node, use $\pi_{\underline{b}_{i} \leftarrow \underline{x}}(x)=\mathcal{N}(!x) \pi_{\underline{x}}(x)$. )
In the above equations, if the range set of a product is empty, then define the product as 1; i.e., $\prod_{k \in \emptyset} F(k)=1$.
Claim: Define

$$
\begin{equation*}
B E L^{(t)}(x)=\mathcal{N}(!x) \lambda_{\underline{x}}^{(t)}(x) \pi_{\underline{x}}^{(t)}(x) . \tag{31.62}
\end{equation*}
$$

Then

$$
\begin{equation*}
\lim _{t \rightarrow \infty} B E L^{(t)}(x)=P(x \mid \epsilon) \tag{31.63}
\end{equation*}
$$

This says that the belief in $\underline{x}=x$ converges to $P(x \mid \epsilon)$ and it equals the product of messages received from all parents and children of $\underline{x}=x$.

### 31.4.1 How BP algo for polytrees reduces to the BP algo for Markov chains

It is instructive to see how the BP algo for polytrees reduces to BP algo for Markov chains.

For a Markov chain, node $\underline{x}$ has a single parent (i.e., ancestor) $\underline{a}$ and a single child $\underline{b}$.

Therefore, Eqs.(31.55) and (31.57) reduce to

$$
\begin{equation*}
\pi_{\underline{x}}(x)=\sum_{a} P(x \mid a) \pi_{\underline{x} \Leftarrow \underline{a}}(a) \tag{31.64}
\end{equation*}
$$

and

$$
\begin{equation*}
\lambda_{\underline{x}}(x)=\lambda_{\underline{b}=\underline{x}}(x) . \tag{31.65}
\end{equation*}
$$

RULE 1 given by Eq. (31.58) reduces to

$$
\begin{align*}
\lambda_{\underline{x} \Rightarrow \underline{a}}(a) & =\mathcal{N}(!a) \sum_{x} \lambda_{\underline{x}}(x) P(x \mid a)  \tag{31.66}\\
& =\mathcal{N}(!a) \sum_{x} \lambda_{\underline{b}=\underline{x}}(x) P(x \mid a) \tag{31.67}
\end{align*}
$$

RULE 2 given by Eq.(31.61) reduces to

$$
\begin{align*}
\pi_{\underline{b} \Leftarrow \underline{x}}(x) & =\mathcal{N}(!x) \pi_{\underline{x}}(x)  \tag{31.68}\\
& =\sum_{a} P(x \mid a) \pi_{\underline{x} \Leftarrow \underline{a}}(a) . \tag{31.69}
\end{align*}
$$

### 31.5 Derivation of BP Algorithm for Polytrees

This derivation is taken from the 1988 book Ref.[25] by Judea Pearl, where it is presented very lucidly. We only made some minor changes in notation.

## Notation

The BP algorithm yields an expansion for $P(x \mid \epsilon)$.
$\underline{x}=$ the focus node, arbitrary node of bnet that we are focusing on to calculate its $P(x \mid \epsilon)$.
$\left(\underline{a}_{i}\right)_{i=0,1, \ldots, n a-1}$. $=$ parent nodes (mnemonic: a=ancestor) of $\underline{x}$
$\left(\underline{b}_{i}\right)_{i=0,1, \ldots, n b-1}=$ children nodes of $\underline{x}$.
$\underline{\epsilon}=$ set of nodes for which there is evidence; that is, $\underline{\epsilon}=\epsilon$, so the state of these nodes is fixed.
$\underline{\epsilon}_{\underline{x}}^{-}=\underline{\epsilon} \cap a n(\underline{x})$ (evidence in past of $\left.\underline{x}\right)^{4}$
$\epsilon_{\underline{x a}}^{i}+\epsilon_{\underline{x}}^{-} \cap a n\left(\underline{a}_{i}\right)$.
Note that $\epsilon_{\underline{x}}^{-}=\cup_{i} \epsilon_{\underline{a_{i}}}^{-}$
$\underline{\epsilon}_{\underline{x}}^{+}=\underline{\epsilon} \cap[d \bar{e}(\underline{x}) \cup \underline{x}]$ (evidence in future of $\underline{x}$ )
$\epsilon_{\underline{x} \underline{b}_{i}}^{+}=\epsilon_{\underline{x}}^{+} \cap\left[d e\left(\underline{b}_{i}\right) \cup \underline{b}_{i}\right]$.
Note that $\epsilon_{\underline{x}}^{+}=\cup_{i} \epsilon_{\underline{x_{b}}}^{i}$
Note that $\underline{\epsilon}=\underline{\epsilon}_{\underline{x}}^{+} \cup \epsilon_{\underline{x}}^{-}$

$$
\begin{gather*}
\pi_{\underline{x}}(x)=P\left(x \mid \epsilon_{\underline{x}}^{-}\right)  \tag{31.70}\\
\pi_{\underline{x} \neq \underline{a}_{i}}\left(a_{i}\right)=P\left(a_{i} \mid \epsilon_{\underline{x a_{i}}}^{-}\right)  \tag{31.71}\\
\pi_{\underline{b}_{i}=\underline{x}}(x)=P\left(x \mid \epsilon_{\underline{x b_{i}}}^{-}\right)  \tag{31.72}\\
\lambda_{\underline{x}}(x)=P\left(\epsilon_{\underline{x}}^{+} \mid x\right)  \tag{31.73}\\
\lambda_{\underline{b}_{i} \Rightarrow \underline{x}}(x)=P\left(\epsilon_{\underline{x b_{i}}}^{+} \mid x\right)  \tag{31.74}\\
\lambda_{\underline{x} \Rightarrow \underline{a}_{i}}\left(a_{i}\right)=P\left(\epsilon_{\underline{x a_{i}}}^{+} \mid a_{i}\right) \tag{31.75}
\end{gather*}
$$

Expansions of $\lambda_{\underline{x}}(x)$ and $\pi_{\underline{x}}(x)$ into products of single node messages.

[^16]\[

$$
\begin{align*}
\underbrace{P\left(x \mid \epsilon_{\underline{x}}^{-}\right)}_{\pi_{\underline{x}}(x)} & =P\left(x \mid \cup_{i} \epsilon_{\underline{x} a_{i}}^{-}\right)  \tag{31.76}\\
& =\sum_{a^{n a}} P\left(x \mid a^{n a}\right) P\left(a^{n a} \mid \cup_{i} \epsilon_{\underline{x a_{i}}}^{-}\right)  \tag{31.77}\\
& =\sum_{a^{n a}} P\left(x \mid a^{n a}\right) \prod \prod_{i} \underbrace{P\left(a_{i} \mid \epsilon_{\epsilon_{x_{i}}^{-}}^{-}\right)}_{\pi_{\underline{x}=\underline{a}_{i}}\left(a_{i}\right)}  \tag{31.78}\\
& \underbrace{P\left(\epsilon_{\underline{x}}^{+} \mid x\right)}_{\lambda_{\underline{x}}(x)}=\prod_{i} \underbrace{P\left(\epsilon_{\underline{x b_{i}}}^{+} \mid x\right)}_{\lambda_{\underline{b_{i}} \boldsymbol{z} \underline{x}}(x)} \tag{31.79}
\end{align*}
$$
\]

Note that past and future evidences $\epsilon_{\underline{x}}^{-}$and $\epsilon_{\underline{x}}^{+}$that are causally connected to $\underline{x}$ are conditionally independent at fixed $\underline{x}$ :

$$
\begin{equation*}
P\left(\epsilon_{\underline{x}}^{+}, \epsilon_{\underline{x}}^{-} \mid x\right)=P\left(\epsilon_{\underline{x}}^{+} \mid x\right) P\left(\epsilon_{\underline{x}}^{-} \mid x\right) . \tag{31.80}
\end{equation*}
$$

This observation is key to the proof of the following claim:

## Claim 23

$$
\begin{align*}
P\left(x \mid \epsilon_{\underline{x}}^{+}, \epsilon_{\underline{x}}^{-}\right) & =P\left(\epsilon_{\underline{x}}^{+} \mid x\right) P\left(x \mid \epsilon_{\underline{x}}^{-}\right) \frac{1}{P\left(\epsilon_{\underline{x}}^{+} \mid \epsilon_{\underline{x}}^{-}\right)}  \tag{31.81}\\
& =\mathcal{N}(!x) P\left(\epsilon_{\underline{x}}^{+} \mid x\right) P\left(x \mid \epsilon_{\underline{x}}^{-}\right)  \tag{31.82}\\
& =\mathcal{N}(!x)\left(\epsilon_{\underline{x}}^{+} \leftarrow x \leftarrow \epsilon_{\underline{x}}^{-}\right)  \tag{31.83}\\
& =\mathcal{N}(!x) \lambda_{\underline{x}}(x) \pi_{\underline{x}}(x) \tag{31.84}
\end{align*}
$$

proof:

$$
\begin{align*}
P\left(x \mid \epsilon_{\underline{x}}^{+}, \epsilon_{\underline{x}}^{-}\right) & =P\left(\epsilon_{\underline{\underline{x}}}^{+}, \epsilon_{\underline{x}}^{-} \mid x\right) \frac{P(x)}{P\left(\epsilon_{\underline{x}}^{+}, \epsilon_{\underline{x}}^{-}\right)}  \tag{31.85}\\
& =P\left(\epsilon_{\underline{x}}^{+} \mid x\right) P\left(\epsilon_{\underline{x}}^{-} \mid x\right) \frac{P(x)}{P\left(\epsilon_{\underline{x}}^{+}, \epsilon_{\underline{x}}^{-}\right)}  \tag{31.86}\\
& =P\left(\epsilon_{\underline{x}}^{+} \mid x\right) P\left(x \mid \epsilon_{\underline{x}}^{-}\right) \frac{P\left(\epsilon_{\underline{x}}^{-}\right)}{P\left(\epsilon_{\underline{x}}^{+}, \epsilon_{\underline{x}}^{-}\right)}  \tag{31.87}\\
& =P\left(\epsilon_{\underline{x}}^{+} \mid x\right) P\left(x \mid \epsilon_{\underline{x}}^{-}\right) \frac{1}{P\left(\epsilon_{\underline{x}}^{+} \mid \epsilon_{\underline{x}}^{-}\right)} \tag{31.88}
\end{align*}
$$

## QED

Next we prove BP rules 1 and 2 .

Figure 31.12: This figure is used in the derivation of the BP RULE 1.

## - RULE 1 (red parent)

Note that

$$
\begin{align*}
\epsilon_{\underline{x}}^{+} \cup \cup_{k \neq i} \epsilon_{\underline{a_{k}}}^{-} & =\left(\epsilon_{\underline{x}}^{+} \cup \epsilon_{\underline{x}}^{-}\right)-\epsilon_{\underline{x a_{i}}}^{-}  \tag{31.89}\\
& =\epsilon_{\underline{x a_{i}}}^{+} \tag{31.90}
\end{align*}
$$

Let $y=\left(a_{k}\right)_{k \neq i}$ and $\epsilon_{\underline{y}}^{-}=\left(\epsilon_{\underline{a_{k}}}^{-}\right)_{k \neq i}$.

$$
\begin{align*}
\underbrace{P\left(\epsilon_{\underline{a_{a}}}^{+} \mid a_{i}\right)}_{\lambda_{\underline{x} \neq \underline{a}_{i}}\left(a_{i}\right)} & =P\left(\epsilon_{\underline{x}}^{+}, \epsilon_{\underline{\underline{y}}}^{-} \mid a_{i}\right)  \tag{31.91}\\
& =\sum_{x} \sum_{y} P\left(\epsilon_{\underline{x}}^{+}, \epsilon_{\underline{y}}^{-} \mid x, y\right) P\left(x, y \mid a_{i}\right)  \tag{31.92}\\
& =\sum_{x} \sum_{y} P\left(\epsilon_{\underline{x}}^{+} \mid x\right) P\left(\epsilon_{\underline{y}}^{-} \mid y\right) P\left(x \mid y, a_{i}\right) P\left(y \mid a_{i}\right)  \tag{31.93}\\
& =P\left(\epsilon_{\underline{y}}^{-}\right) \sum_{x} \sum_{y} P\left(\epsilon_{\underline{x}}^{+} \mid x\right) \frac{P\left(y \mid \epsilon_{\underline{y}}^{-}\right)}{P(y)} P\left(x \mid y, a_{i}\right) \underbrace{P\left(y \mid a_{i}\right)}_{=P(y)}  \tag{31.94}\\
& =\mathcal{N}\left(!a_{i}\right) \sum_{x} \sum_{y} P\left(\epsilon_{\underline{x}}^{+} \mid x\right) P(x \mid \underbrace{y, a_{i}}_{a^{n a}}) P\left(y \mid \epsilon_{\underline{y}}^{-}\right)  \tag{31.95}\\
& =\mathcal{N}\left(!a_{i}\right) \sum_{x} \underbrace{P\left(\epsilon_{\underline{x}}^{+} \mid x\right)}_{\lambda_{\underline{x}}(x)} \sum_{\left(a_{k}\right)_{k \neq i}} P\left(x \mid a^{n a}\right) \prod_{k \neq i} \underbrace{P\left(a_{k} \mid \epsilon_{\underline{x_{k}} \underline{a}_{k}}^{-}\right)}_{\pi_{\underline{x} \div \underline{a}_{k}}\left(a_{k}\right)} \tag{31.96}
\end{align*}
$$

Figure 31.13: This figure is used in the derivation of the BP RULE 2.

## - RULE 2 (red child)

Note that

$$
\begin{align*}
& \left(\cup_{k \neq i} \epsilon_{\underline{x b_{k}}}^{+}\right) \cup \epsilon_{\underline{x}}^{-}=\left(\epsilon_{\underline{x}}^{+} \cup \epsilon_{\underline{x}}^{-}\right)-\epsilon_{\underline{x b_{i}}}^{+}  \tag{31.97}\\
& =\epsilon_{\underline{x b_{i}}}^{-}  \tag{31.98}\\
& \underbrace{P\left(x \mid \epsilon_{\underline{b_{i}}}^{-}\right)}_{\pi_{\underline{b}_{i} \in \underline{x}}(x)}=P\left(x \mid\left(\epsilon_{\underline{x b_{k}}}^{+}\right)_{k \neq i}, \epsilon_{\underline{x}}^{-}\right)  \tag{31.99}\\
& =\mathcal{N}(!x) P\left(\left(\epsilon_{\underline{x b}_{k}}^{+}\right)_{k \neq i} \mid x\right) P\left(x \mid \epsilon_{\underline{x}}^{-}\right)  \tag{31.100}\\
& =\mathcal{N}(!x)(\prod_{k \neq i} \underbrace{P\left(\epsilon_{\underline{x b_{k}}}^{+} \mid x\right)}_{\lambda_{\underline{b}_{k} \Rightarrow \underline{x}}(x)}) \underbrace{P\left(x \mid \epsilon_{\underline{x}}^{-}\right)}_{\pi_{\underline{\underline{x}}}(x)} \tag{31.101}
\end{align*}
$$

### 31.6 Example of BP algo for a Tree

In this section, we describe how to apply the BP algo to the tree bnet Fig.31.14. In Fig 31.14 , if we replace each integer $i$ by the random variable $\underline{A}_{i}$, we get an original bnet, and if we replace each $i$ by $\underline{\mathcal{M}}_{\underline{A}_{i}}$, we get the BP memory bnet of the original bnet. In Fig. 31.14 , the magenta nodes are evidence nodes and the green ones aren't.

We want to solve for the memory matrices of the memory bnet. To do so, we use the BP dynamic bnet Fig 31.15 . The steps encoded in the dynamic bnet are shown in Fig.31.16. Fig.31.16 has frames in chronological order, showing the direction of travel of the $\pi \& \lambda$ information. This sequence of frames also indicates the order in which we solve for the entries of the memory matrices. The information first emanates from the evidence nodes. It propagates generally upstream, although some nodes can generate downstream flow. Some of the info reaches the root node and is reflected there. The root node is the only one that is capable of reflection (i.e., instant output along an arrow, in response to input along that arrow). Eventually, all info reaches the leaf nodes via downstream propagation and is absorbed there.

Figure 31.14: Example tree bnet used to illustrate BP.

Figure 31.15: BP dynamic bnet for the bnet Fig 31.14 .

Figure 31.16: Steps encoded in the bnet Fig 31.15 .

### 31.7 Bipartite bnets

By a bipartite bnet we will mean a bnet in which all nodes are either root nodes (parentless) or leaf nodes (childless). BP simplifies when dealing with bipartite bnets. In this section, we will explain how it simplifies. But before doing so, let us explain how the following two types of diagrams can be replaced by equivalent bipartite bnets:

- Factor Graphs
- Tree bnets

Consider a product $g=\prod_{\alpha} f_{\alpha}$ of scalar functions $f_{\alpha}: S_{\underline{x}_{0}} \times S_{\underline{x}_{1}} \times \ldots S_{\underline{x}_{n x-1}} \rightarrow \mathbb{R}$ for $\alpha=0,1, \ldots, n f-1$. For instance, consider $g: S_{\underline{x}_{0}} \times S_{\underline{x}_{1}} \times S_{\underline{x}_{2}} \rightarrow \mathbb{R}$ defined by:

$$
\begin{equation*}
g\left(x_{0}, x_{1}, x_{2}\right)=f_{0}\left(x_{0}\right) f_{1}\left(x_{0}, x_{1}\right) f_{2}\left(x_{0}, x_{1}\right) f_{3}\left(x_{1}, x_{2}\right) \tag{31.102}
\end{equation*}
$$

The factor graph for this function $g$ is given by Fig.31.17.

Figure 31.17: Factor graph for function $g$ defined by Eq. 31.102).

Figure 31.18: Bipartite bnet corresponding to factor graph Fig 31.17 .

One can map any factor graph (the "source") to a special bipartite bnet (the "image"), as follows. Replace each $x_{i}$ by $\underline{x}_{i} \in S_{\underline{x}_{i}}$ for $i=0,1, \ldots, n x-1$ and each $f_{\alpha}$ by $\underline{f}_{\alpha}$ for $\alpha=0,1, \ldots, n f-1$. Then replace the connections (edges) of the factor graph by arrows from $\underline{x}_{i}$ to $f_{\alpha}$. For example, Fig 31.18 is the image bipartite bnet of the source factor graph Fig 31.17 .

Let $\underline{x}^{n x}=\left(\underline{x}_{0}, \underline{x}_{1}, \ldots, \underline{x}_{n x-1}\right)$ and $\underline{f}^{n f}=\left(\underline{f}_{0}, \underline{f}_{1}, \ldots, \underline{f}_{n f-1}\right)$. Let ${ }^{5} f_{\alpha} \in\{0,1\}$ for all $\alpha$, and $y_{\alpha}=f_{\alpha}\left(x_{n b\left(\underline{f}_{\alpha}\right)}\right)$. Here we are using $n b\left(\underline{f}_{\alpha}\right)$ to denote the neighborhood of node $\underline{f}_{\alpha}$ in the image bipartite bnet, and we are using $x_{S}$ to denote $\left(x_{i}\right)_{i \in S}$. Without loss of generality, we will assume that $y_{\alpha} \in[0,1]$ for all $\alpha$. Then we define the node TPMs, printed in blue, for the image bipartite bnet, as follows.

$$
\begin{equation*}
P\left(f_{\alpha} \mid x_{n x\left(f_{\alpha}\right)}\right)=y_{\alpha} \delta\left(f_{\alpha}, 1\right)+\left[1-y_{\alpha}\right] \delta\left(f_{\alpha}, 0\right) \tag{31.103}
\end{equation*}
$$

for $\alpha=0,1, \ldots, n f-1$ and

$$
\begin{equation*}
P_{\underline{x}_{i}}\left(x_{i}\right)=\text { arbitrary prior } \tag{31.104}
\end{equation*}
$$

for $i=0,1, \ldots, n x-1$.
Note that

$$
\begin{equation*}
P\left(f^{n f}=1^{n f} \mid x^{n x}\right)=\prod_{\alpha} f_{\alpha}\left(x_{n b\left(\underline{f}_{\alpha}\right)}\right) . \tag{31.105}
\end{equation*}
$$

A tree bnet is a bnet for which all nodes have exactly one parent except for the apex root node which has none. A tree bnet is very much like the filing system in a computer.

One can map a tree bnet (the "source") into an equivalent bipartite bnet (the "image") as follows. Replace each arrow

$$
\begin{equation*}
\underline{x} \longrightarrow \underline{y} \tag{31.106}
\end{equation*}
$$

of the tree bnet by

$$
\begin{equation*}
\underline{x} \longrightarrow \underline{P_{\underline{y} \mid \underline{x}}} \longleftarrow \underline{y} . \tag{31.107}
\end{equation*}
$$

For example, the tree bnet Fig 31.19 has the image bipartite bnet given by Fig 31.20 . The bnet Fig 31.21 is just a different way of drawing the bnet Fig 31.20 .

The node TPMs, printed in blue, for the image bipartite bnet Fig 31.20, are as follows. We express the TPMs of the image bnet in terms of the TPMs of the source bnet Fig.31.19, Let

$$
\begin{equation*}
P\left(P_{\underline{y} \mid \underline{x}} \mid x, y\right)=P_{\underline{y} \mid \underline{\mid x}}(y \mid x) \delta\left(P_{\underline{y} \mid \underline{\mid}, \underline{x}}, 1\right)+\left(1-P_{\underline{y} \mid \underline{x}}(y \mid x)\right) \delta\left(P_{\underline{y} \mid \underline{x}}, 0\right) \tag{31.108}
\end{equation*}
$$

for all the leaf nodes $P_{\underline{y} \mid \underline{x}} \in\{0,1\}$ of the image bipartite bnet. Also, let

$$
\begin{equation*}
P_{\underline{y}}(y)=\text { arbitrary prior } \tag{31.109}
\end{equation*}
$$

[^17]

Figure 31.19: Example of a tree bnet.

Figure 31.20: Bipartite bnet corresponding to tree bnet Fig 31.19 .

Figure 31.21: Different way of drawing the bnet Fig 31.20 .
for all the root nodes $\underline{y}$ of the image bipartite bnet except when $\underline{y}$ corresponds to the root node $\underline{A}$ of the source tree bnet. In that exceptional case,

$$
\begin{equation*}
P_{\underline{y}}(y)=P_{\underline{A}}(y) . \tag{31.110}
\end{equation*}
$$

### 31.8 BP for bipartite bnets (BP-BB)

For a bipartite bnet as defined above, with root nodes $\underline{x}_{i}$ and leaf nodes $\underline{f}_{\alpha}$, let

$$
\begin{gather*}
n b(i)=\left\{\alpha: \underline{f}_{\alpha} \in n b\left(\underline{x}_{i}\right)\right\},  \tag{31.111}\\
n b(\alpha)=\left\{i: \underline{x}_{i} \in n b\left(\underline{f}_{\alpha}\right)\right\},  \tag{31.112}\\
m_{\alpha \Leftarrow i}\left(x_{i}\right)=\pi_{\underline{f}_{\alpha} \in \underline{x}_{i}}\left(x_{i}\right),  \tag{31.113}\\
m_{\alpha \Rightarrow i}\left(x_{i}\right)=\lambda_{\underline{f}_{\alpha} \Rightarrow \underline{x}_{i}}\left(x_{i}\right), \tag{31.114}
\end{gather*}
$$

$$
m_{\underline{f}_{2}} \Rightarrow \underline{x}_{2}
$$

$$
m_{\underline{f}_{2}} \Leftarrow \underline{x}_{2}
$$

Figure 31.22: Fig 31.11 becomes this figure for the special case of a bipartite bnet. Union of green nodes and the red node $=$ full neighborhood of yellow node. There are two possible cases: the red node is either a parent or a child of the yellow node.

Next we will show how to find $m_{\alpha \Leftarrow i}^{(t)}$ and $m_{\alpha \Rightarrow i}^{(t)}$ from $m_{\alpha \Leftarrow i}^{(t-1)}$ and $m_{\alpha \Rightarrow i}^{(t-1)}$.

1. Traversing an $x$ (i.e., root) node.

See the $m_{\underline{f}_{2} \leftarrow \underline{x}_{2}}$ panel of Fig 31.22 .
For $i=0,1, \ldots, n x-1$, if $\alpha \in n b(i)$, then,

$$
\begin{equation*}
m_{\alpha \Leftarrow i}^{(t)}\left(x_{i}\right)=\prod_{\beta \in n b(i)-\alpha} m_{\beta \Rightarrow i}^{(t-1)}\left(x_{i}\right), \tag{31.115}
\end{equation*}
$$

whereas if $\alpha \notin n b(i)$

$$
\begin{equation*}
m_{\alpha \Leftarrow i}^{(t)}\left(x_{i}\right)=m_{\alpha \Leftarrow i}^{(t-1)}\left(x_{i}\right) . \tag{31.116}
\end{equation*}
$$

2. Traversing an $f$ (i.e., leaf) node.

See the $m_{\underline{f}_{2} \Rightarrow \underline{x}_{2}}$ panel of Fig 31.22 .

For $\alpha=0,1, \ldots, n f-1$, if $i \in n b(\alpha)$, then

$$
\begin{align*}
m_{\alpha \Rightarrow i}^{(t)}\left(x_{i}\right) & =\sum_{\left(x_{k}\right)_{k \in n b(\alpha)-i}} f_{\alpha}\left(x_{n b(\alpha)}\right) \prod_{k \in n b(\alpha)-i} m_{\alpha \Leftarrow k}^{(t-1)}\left(x_{k}\right)  \tag{31.117}\\
& =E_{\left(x_{k}\right)_{k \in n b(\alpha)-i}^{(t-1)}}\left[f_{\alpha}\left(x_{n b(\alpha)}\right)\right] \tag{31.118}
\end{align*}
$$

whereas if $i \notin n b(\alpha)$

$$
\begin{equation*}
m_{\alpha \Rightarrow i}^{(t)}\left(x_{i}\right)=m_{\alpha \Rightarrow i}^{(t-1)}\left(x_{i}\right) . \tag{31.119}
\end{equation*}
$$

In the above equations, if the range set of a product is empty, then define the product as 1; i.e., $\prod_{k \in \emptyset} F(k)=1$.

## Claim:

$$
\begin{equation*}
P\left(x_{i} \mid \epsilon\right)=\lim _{t \rightarrow \infty} \mathcal{N}\left(!x_{i}\right) \prod_{\alpha \in n b(i)} m_{\alpha \Rightarrow i}^{(t)}\left(x_{i}\right) \tag{31.120}
\end{equation*}
$$

and

$$
\begin{equation*}
P\left(x_{n b(\alpha)} \mid \epsilon\right)=\lim _{t \rightarrow \infty} \mathcal{N}\left(!x_{n b(\alpha)}\right) f_{\alpha}\left(x_{n b(\alpha)}\right) \prod_{k \in n b(\alpha)} m_{\alpha \Leftarrow k}^{(t)}\left(x_{k}\right) . \tag{31.121}
\end{equation*}
$$

### 31.8.1 BP-BB and general BP agree on Markov chains

It is instructive to compare the belief values (i.e., $P\left(x_{i} \mid \epsilon\right)$ ) obtained by applying the general (i.e., polytree) BP and BP-BB algorithms to a Markov chain. Next we show that both algorithms yield the same belief values.

Figure 31.23: Traversing a root node of a Markov chain (a)Propagation towards left (i.e., towards future). (b)Propagation towards right (i.e., towards past).

Consider the BP-BB rule for traversing a root node. When traveling towards the left as in Fig 31.23 (a), it implies that

$$
\begin{equation*}
m_{\alpha \Rightarrow 2}\left(x_{2}\right)=m_{\beta \Leftarrow 2}\left(x_{2}\right), \tag{31.122}
\end{equation*}
$$

and when traveling towards the right as in Fig 31.23 (b), it implies that

$$
\begin{equation*}
m_{\beta \Rightarrow 2}\left(x_{2}\right)=m_{\alpha \Leftarrow 2}\left(x_{2}\right) . \tag{31.123}
\end{equation*}
$$

Figure 31.24: Traversing a leaf node of a Markov chain (a)Propagation towards left (i.e., towards future). (b)Propagation towards right (i.e., towards past).

Now consider the BP-BB rule for traversing a leaf node. When traveling to the left as in Fig. 31.24 (a), it implies that

$$
\begin{equation*}
\underbrace{m_{\alpha \Rightarrow 2}\left(x_{2}\right)}_{\lambda}=\sum_{x_{1}} P\left(x_{2} \mid x_{1}\right) \underbrace{m_{\alpha \Leftarrow 1}\left(x_{1}\right)}_{\pi} . \tag{31.124}
\end{equation*}
$$

One can rewrite the left and right hand sides (LHS, RHS) of Eq. 31.124 ) as follows

$$
\begin{equation*}
R H S=\sum_{x_{1}} P\left(x_{2} \mid x_{1}\right) \pi_{\alpha \Leftarrow 1}\left(x_{1}\right), \tag{31.125}
\end{equation*}
$$

and

$$
\begin{equation*}
L H S=m_{\alpha \not 2}\left(x_{2}\right)=m_{\beta \Leftarrow 2}\left(x_{2}\right)=\pi_{\beta \Leftarrow 2}\left(x_{2}\right), \tag{31.126}
\end{equation*}
$$

Therefore

$$
\begin{equation*}
\pi_{\beta \Leftarrow 2}\left(x_{2}\right) \sum_{x_{1}} P\left(x_{2} \mid x_{1}\right) \pi_{\alpha \Leftarrow 1}\left(x_{1}\right) . \tag{31.127}
\end{equation*}
$$

Once again, consider the BP-BB rule for traversing a leaf node. When traveling to the right as in Fig 31.24 (b), it implies that

$$
\begin{equation*}
\underbrace{m_{\alpha \Rightarrow 1}\left(x_{1}\right)}_{\lambda}=\sum_{x_{2}} P\left(x_{2} \mid x_{1}\right) \underbrace{m_{\alpha \leftarrow 2}\left(x_{2}\right)}_{\pi} . \tag{31.128}
\end{equation*}
$$

One can rewrite the left and right hand sides (LHS, RHS) of Eq. 31.128) as follows

$$
\begin{align*}
R H S= & =\sum_{x_{2}} P\left(x_{2} \mid x_{1}\right) \pi_{\alpha \Leftarrow 2}\left(x_{2}\right)  \tag{31.129}\\
& =\sum_{x_{2}} P\left(x_{2} \mid x_{1}\right) \lambda_{\beta \Rightarrow 2}\left(x_{2}\right), \tag{31.130}
\end{align*}
$$

and

$$
\begin{equation*}
L H S=\lambda_{\alpha \Rightarrow 1}\left(x_{1}\right) . \tag{31.131}
\end{equation*}
$$

Therefore,

$$
\begin{equation*}
\lambda_{\alpha \Rightarrow 1}\left(x_{1}\right)=\sum_{x_{2}} P\left(x_{2} \mid x_{1}\right) \lambda_{\beta \Rightarrow 2}\left(x_{2}\right) \tag{31.132}
\end{equation*}
$$

Finally, note that Eq. 31.120 becomes

$$
\begin{align*}
P\left(x_{2} \mid \epsilon\right) & =\mathcal{N}\left(!x_{2}\right) m_{\beta \Rightarrow 2}\left(x_{2}\right) m_{\alpha \Rightarrow 2}\left(x_{2}\right)  \tag{31.133}\\
& =\mathcal{N}\left(!x_{2}\right) m_{\alpha \Leftarrow 2}\left(x_{2}\right) m_{\alpha \Rightarrow 2}\left(x_{2}\right)  \tag{31.134}\\
& =\mathcal{N}\left(!x_{2}\right) \pi_{\alpha \Leftarrow 2}\left(x_{2}\right) \lambda_{\alpha=2}\left(x_{2}\right)  \tag{31.135}\\
& =\mathcal{N}\left(!x_{2}\right) P\left(x_{2} \mid \epsilon^{-}\right) P\left(x_{2} \mid \epsilon^{+}\right) \tag{31.136}
\end{align*}
$$

and Eq.(31.121) becomes

$$
\begin{align*}
P\left(x_{2}, x_{1}\right) & =\mathcal{N}\left(!x_{2},!x_{1}\right) P\left(x_{2} \mid x_{1}\right) m_{\alpha \Leftarrow 1}\left(x_{1}\right) m_{\alpha \Leftarrow 2}\left(x_{2}\right)  \tag{31.137}\\
& =\mathcal{N}\left(!x_{2},!x_{1}\right) P\left(x_{2} \mid x_{1}\right) \pi_{\alpha \Leftarrow 1}\left(x_{1}\right) \pi_{\alpha \Leftarrow 2}\left(x_{2}\right) . \tag{31.138}
\end{align*}
$$

### 31.8.2 BP-BB and general BP agree on tree bnets.

It is instructive to compare the belief values (i.e., $P\left(x_{i} \mid \epsilon\right)$ ) obtained by applying the general (i.e., polytree) BP and BP-BB algorithms to a tree bnet. Next we show that both algorithms yield the same belief values.

Applying to the left panel of Fig 31.25 the BP-BB rule for traversing a root node, we get

$$
\begin{equation*}
m_{\alpha \Leftarrow \underline{x}}(x)=\prod_{i} m_{\beta_{i} \Rightarrow \underline{x}}(x) . \tag{31.139}
\end{equation*}
$$

Applying to the left panel of Fig 31.25 the BP-BB rule for traversing a leaf node, we get

$$
\begin{equation*}
m_{\alpha \Rightarrow \underline{a}}(a)=\mathcal{N}(!a) \sum_{x} m_{\alpha \Leftarrow \underline{x}}(x) P(x \mid a) . \tag{31.140}
\end{equation*}
$$

Combining Eqs.(31.139) and (31.140), we get

$$
\begin{equation*}
m_{\alpha \Rightarrow \underline{a}}(a)=\mathcal{N}(!a) \sum_{x} P(x \mid a) \prod_{i} m_{\beta_{i} \Rightarrow \underline{x}}(x), \tag{31.141}
\end{equation*}
$$

Figure 31.25: Subgraph of a tree bnet. This is the same as Fig 31.11, except that here the yellow node has a single parent because this is a subgraph of a tree bnet, not of an arbitrary bnet like Fig.31.11. The subgraph has been converted to a subgraph of a bipartite bnet by inserting a collider leaf node, labeled by a Greek letter, at the center of each edge of the tree bnet. Red arrows indicate the direction of message info flow.
which can be rewritten as

$$
\begin{equation*}
\lambda_{\underline{x} \Rightarrow \underline{a}}(a)=\mathcal{N}(!a) \sum_{x} P(x \mid a) \underbrace{\prod_{i} \lambda_{\underline{b}_{i} \Rightarrow \underline{x}}(x)}_{\lambda_{\underline{x}}(x)} . \tag{31.142}
\end{equation*}
$$

Eq. 31.142 is just RULE 1 for general BP.
Applying to the right panel of Fig 31.25 the BP-BB rule for traversing a root node, we get

$$
\begin{equation*}
m_{\beta_{i} \leftarrow \underline{x}}(x)=\mathcal{N}(!x) m_{\alpha \Rightarrow \underline{x}}(x) \prod_{k \neq i} m_{\beta_{k} \Rightarrow \underline{x}}(x) \tag{31.143}
\end{equation*}
$$

Applying to the right panel of Fig 31.25 the BP-BB rule for traversing a leaf node, we get

$$
\begin{align*}
m_{\alpha \Rightarrow \underline{x}}(x) & =\sum_{a} P(x \mid a) m_{\alpha \Leftarrow a}(a)  \tag{31.144}\\
& =\sum_{a} P(x \mid a) \pi_{\underline{x} \Leftarrow a}(a)  \tag{31.145}\\
& =\pi_{\underline{x}}(x) . \tag{31.146}
\end{align*}
$$

Combining Eqs. (31.143) and (31.146), we get

$$
\begin{equation*}
\pi_{\underline{b}_{i} \notin \underline{x}}(x)=\mathcal{N}(!x) \pi_{\underline{x}}(x) \prod_{k \neq i} \lambda_{\underline{b}_{k} \Rightarrow \underline{x}}(x) . \tag{31.147}
\end{equation*}
$$

Eq. 31.147) is just RULE 2 of general BP.

## $31.9 \quad \mathrm{BP}-\mathrm{BB}$ and sum-product decomposition

BP-BB yields what is often referred to as a sum-product decomposition. I don't like that name because it is unnecessarily confusing, and it fails to convey the recursive natur $\epsilon^{6}$ of the decomposition. I prefer to call it a recursive sum of products (RSOP) decomposition, and will call it so henceforth in this chapter.

Expressing the marginals of a bnet as RSOPs, which is what BP does, reduces the complexity of the calculation. (i.e., the total number of additions and multiplications that need to be performed) That makes using the BP algo very advantageous. For instance, consider a Markov chain $\underline{x}_{n-1} \leftarrow \cdots \leftarrow \underline{x}_{1} \leftarrow \underline{x}_{0}$, where $x_{i} \in\{0,1,2\}$ for all $i$. Note that if we calculate $P\left(x_{n-1}\right)$ as follows

$$
\begin{equation*}
P\left(x_{n-1}\right)=\left[\sum_{x_{n-2}} P\left(x_{n-1} \mid x_{n-2}\right) \ldots\left[\sum_{x_{1}} P\left(x_{2} \mid x_{1}\right)\left[\sum_{x_{0}} P\left(x_{1} \mid x_{0}\right) P\left(x_{0}\right)\right]\right] \ldots\right], \tag{31.148}
\end{equation*}
$$

we need to perform $2(n-1)$ additions and $3(n-1)$ multiplications. On the other hand, if we calculate $P\left(x_{n-1}\right)$ as follows

$$
\begin{equation*}
P\left(x_{n-1}\right)=\sum_{x_{n-2}} \ldots \sum_{x_{1}} \sum_{x_{0}} P\left(x_{n-1} \mid x_{n-2}\right) \ldots P\left(x_{2} \mid x_{1}\right) P\left(x_{1} \mid x_{0}\right) P\left(x_{0}\right) \tag{31.149}
\end{equation*}
$$

we need to perform $3^{n}-1$ additions and $3^{n}(n-1)$ multiplications.

[^18]
## Chapter 32

## Missing Data, Imputation

This chapter assumes that the reader has read some parts of Chapter 16 on the Expectation Maximization (EM) algo and Chapter 29 on Markov Chain Monte Carlo (MCMC).

|  | $h_{0}$ | $x_{0}$ | $x_{1}$ | $x_{2}$ |
| :--- | :--- | :--- | :--- | :--- |
| 1 | NA | 0 | 1 | 1 |
| 2 | NA | 0 | 0 | 0 |
| 3 | NA | 1 | 1 | 0 |
| 4 | NA | NA | 1 | NA |
| 5 | NA | 0 | NA | 1 |

| 6 | NA | 0 | 0 | 1 | $(0,0,0)$ |

Table 32.1: Left Table: Dataset with $n s a m=6$ and some missing entries, for 4 binary variables $h_{0}, x_{0}, x_{1}, x_{2}$. NA $=$ not available. The $h_{0}$ column is completely missing because $h_{0}$ is an unobserved latent variable. Right Table: All possibilities for $x_{i}=N A$ cells of left table have been enumerated. A new column labeled $m$ has been added. $m_{i}=\mathbb{1}\left(x_{i}\right.$ is missing $)$ for $i=0,1,2$.

Suppose that you have compiled a dataset $\vec{x}=(x[\sigma])_{\sigma=0,1, \ldots, n s a m-1}$ where $x=\left(x_{0}, x_{1}, \ldots, x_{n x-1}\right)$ from a study or survey. It consists of $n s a m$ number of samples (sample $=$ row), and $n x$ columns (each column is a different feature, or observation). Suppose that some of the cells in this matrix are empty. Throwing away all the incomplete rows is okay if the number of incomplete rows is much smaller than nsam. If not, throwing them away would throw away a substantial amount of information contained in all the filled cells in those incomplete rows, plus it might bias your dataset. This chapter deals with how to fill those empty cells with plausible fake data. A fancy name for this process is imputation. There is no unique way of
fabricating fake data, but some fakes are better than others by some metrics. This chapter will consider two popular ways (EM and MCMC) of filling those empty cells with their "most likely" values based on the cells of the dataset that aren't missing, and also based on some bnet model that is expected to describe well the dataset.

Notation: $\underline{\vec{a}}=(\underline{a}[\sigma])_{\sigma=0,1, \ldots, n s a m-1}$, where $n$ sam is the number of samples. Will sometimes denote $a[\sigma]$ by $a^{[\sigma]}$.

For concreteness, we will apply the concepts of this chapter to the dataset with missing data given by Table 32.1.

### 32.1 Imputation via EM

We begin by augmenting Fig. 16.1 (the first figure in Chapter 16) by adding to it a new node $\underline{\vec{m}}$ called the missingness variable. Recall that node $\underline{\theta}$ represents the unknown parameters, node $\underline{\vec{x}}$ represents the observed variables, and node $\vec{h}$ represents the latent variables. Both $\underline{\theta}$ and $\underline{\vec{h}}$ are hidden (i.e., unobserved). Fig 32.1 shows 3 popular ways of connecting node $\underline{\vec{m}}$ to the other nodes in the graph Fig 16.1.

Seldom assumed

MAR

not-MAR (NMAR)

Figure 32.1: The left bnet is seldom assumed. The middle bnet is referred to as the MAR (missing at random) assumption. The right bnet is referred to as the not-MAR (NMAR) assumption.

From Fig 32.1, we have

$$
P(\vec{m} \mid \vec{x}, \vec{h}, \theta)= \begin{cases}P(\vec{m} \mid \theta) & \text { Seldom assumed. Called missing-CAR (MCAR) }  \tag{32.1}\\ P(\vec{m} \mid \vec{x}, \theta) & \text { MAR } \\ P(\vec{m} \mid \vec{x}, \vec{h}, \theta) & \text { not-MAR (NMAR) }\end{cases}
$$

For doing imputation via EM, we connect node $\underline{\vec{m}}$ as shown in the middle bnet (called MAR) of Fig 32.1.

For the example of Table 32.1, we have variables $\underline{\vec{m}}, \underline{\vec{x}}$ and $\underline{\vec{h}}$ whose values range over the following sets:

$$
\begin{aligned}
& \overrightarrow{\vec{x}}=\left(\vec{x}_{0}, \vec{x}_{1}, \vec{x}_{2}\right) \\
& \overrightarrow{\vec{h}}=\left(\overrightarrow{\underline{h}}_{0}\right) \\
& \underline{\underline{h}}_{0}[\sigma] \in\{0,1\}, \\
& \underline{x}_{i}[\sigma] \in\{0,1\} \text { for } i=0,1,2,
\end{aligned}
$$

Figure 32.2: MAR bnet with $n s a m=3$.

Figure 32.3: Our example for imputation via EM assumes this bnet between nodes $\underline{m}[\sigma], \underline{x}[\sigma], \underline{h}[\sigma]$.

$$
\underline{\underline{m}}_{i}[\sigma] \in\{0,1\} \text { for } i=0,1,2 .
$$

For concreteness, we will assume that the Markov chain $\underline{m}[\sigma] \leftarrow \underline{x}[\sigma] \leftarrow \underline{h}[\sigma]$ has a finer grained DAG structure given by Fig. 32.3. where we will omit the dashed arrows. If one doesn't want to assume that the data can be fitted well by the bnet of Fig 32.3 without the dashed arrows, one can include those arrows too, at the expense of more unknown parameters (i.e., degrees of freedom) to be lumped into $\theta$. We will parmaterize the TPMs corresponding to Fig 32.3 using a Categorical Distribution for each column of the TPMs. We will thus assume that the bnet of Fig 32.3 has the following TPMs, printed in blue.

$$
\begin{align*}
& P\left(h_{0}^{[\sigma]} \mid \theta\right)=\begin{array}{l|l} 
& 1-\theta_{0} \\
1 & \theta_{0}
\end{array}  \tag{32.2}\\
& P\left(x_{0}^{[\sigma]} \mid \theta\right)=\begin{array}{l|l}
\hline 0 & 1-\theta_{1} \\
1 & \theta_{1}
\end{array} \tag{32.3}
\end{align*}
$$

$$
\begin{align*}
& P\left(x_{1}^{[\sigma]} \mid x_{0}^{[\sigma]}, h^{[\sigma]}, \theta\right)=\begin{array}{lllll} 
& 00 & 01 & 10 & 11 \\
\hline 0 & 1-\theta_{2} & 1-\theta_{3} & 1-\theta_{4} & 1-\theta_{5} \\
1 & \theta_{2} & \theta_{3} & \theta_{4} & \theta_{5}
\end{array}  \tag{32.4}\\
& P\left(x_{2}^{[\sigma]} \mid x_{1}^{[\sigma]}, x_{0}^{[\sigma]}, \theta\right)=\begin{array}{lllll} 
& 00 & 01 & 10 & 11 \\
\hline 0 & 1-\theta_{6} & 1-\theta_{7} & 1-\theta_{8} & 1-\theta_{9} \\
1 & \theta_{6} & \theta_{7} & \theta_{8} & \theta_{9}
\end{array}  \tag{32.5}\\
& \quad P\left(m^{[\sigma]} \mid x^{[\sigma]}, \theta\right)=\frac{1}{n s a m} P\left(\left(x_{i}\right)_{\forall i \ni m_{i}=1} \mid\left(x_{i}\right)_{\forall i \ni m_{i}=0}, \theta\right) \tag{32.6}
\end{align*}
$$

Eq.(32.6) can be illustrated as follows. In Table 32.2 , we added a $P(m)$ column to Table 32.1 .

|  | $h_{0}$ | $x_{0}$ | $x_{1}$ | $x_{2}$ | $m$ | $P(m)$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 1 | NA | 0 | 1 | 1 | $(0,0,0)$ | $\frac{1}{n s a m}$ |
| 2 | NA | 0 | 0 | 0 | $(0,0,0)$ | $\frac{1}{n s a m}$ |
| 3 | NA | 1 | 1 | 0 | $(0,0,0)$ | $\frac{1}{n s a m}$ |
|  |  | 0 |  | 0 |  | $\frac{1}{n s a m} P\left(x_{0}=0, x_{2}=0 \mid x_{1}=1, \theta\right)$ |
| 4 | NA | 0 | 1 | 1 | $(1,0,1)$ | $\frac{1}{n s a m} P\left(x_{0}=0, x_{2}=1 \mid x_{1}=1, \theta\right)$ |
|  | 1 |  | 0 | $\frac{1}{n s a m} P\left(x_{0}=1, x_{2}=0 \mid x_{1}=1, \theta\right)$ |  |  |
|  | 1 |  | 1 |  | $\frac{1,}{n \text { sam }} P\left(x_{0}=1, x_{2}=1 \mid x_{1}=1, \theta\right)$ |  |
| 5 | NA | 0 | 0 | 1 | $(0,1,0)$ | $\frac{1}{n s a m} P\left(x_{1}=0 \mid x_{0}=0, x_{2}=1, \theta\right)$ |
| 6 | NA | 0 | 0 | 1 | $(0,0,0)$ | $\frac{1}{n \text { sam }} P\left(x_{1}=1 \mid x_{0}=0, x_{2}=1, \theta\right)$ |
| $n s a m$ |  |  |  |  |  |  |

Table 32.2: $P(m)$ column added to Table 32.1. Note that $\sum_{m} P(m)=1$.

$$
\begin{gather*}
\theta=\left(\theta_{i}\right)_{i=0,1, \ldots, 9}  \tag{32.7}\\
P\left(m^{[\sigma]}, x^{[\sigma]}, h^{[\sigma]} \mid \theta\right)=P\left(m^{[\sigma]} \mid x^{[\sigma]}, \theta\right) P\left(x^{[\sigma]} \mid h^{[\sigma]}, \theta\right) P\left(h^{[\sigma]} \mid \theta\right)  \tag{32.8}\\
P\left(x^{[\sigma]} \mid h^{[\sigma]}, \theta\right)=P\left(x_{2}^{[\sigma]} \mid x_{1}^{[\sigma]}, x_{0}^{[\sigma]}, \theta\right) P\left(x_{1}^{[\sigma]} \mid x_{0}^{[\sigma]}, h^{[\sigma]}, \theta\right) P\left(x_{0}^{[\sigma]} \mid \theta\right)  \tag{32.9}\\
P\left(x_{1}^{[\sigma]} \mid x_{0}^{[\sigma]}, \theta\right)=\sum_{h} P\left(x_{1}^{[\sigma]} \mid x_{0}^{[\sigma]}, h^{[\sigma]}, \theta\right) P\left(h^{[\sigma]} \mid \theta\right)  \tag{32.10}\\
P\left(x^{[\sigma]} \mid \theta\right)=P\left(x_{2}^{[\sigma]} \mid x_{1}^{[\sigma]}, x_{0}^{[\sigma]}, \theta\right) P\left(x_{1}^{[\sigma]} \mid x_{0}^{[\sigma]}, \theta\right) P\left(x_{0}^{[\sigma]} \mid \theta\right) \tag{32.11}
\end{gather*}
$$

$$
\begin{align*}
Q\left(\theta \mid \theta^{(t)}\right) & =\sum_{\vec{m}, \vec{h}} P\left(\vec{m}, \vec{h} \mid \vec{x}, \theta^{(t)}\right) \ln P(\vec{m}, \vec{x}, \vec{h} \mid \theta)  \tag{32.12}\\
& =\sum_{\vec{m}, \vec{h}}\left[\prod_{\sigma} P\left(m^{[\sigma]}, h^{[\sigma]} \mid x^{[\sigma]}, \theta^{(t)}\right)\right] \ln \left[\prod_{\sigma} P\left(m^{[\sigma]}, x^{[\sigma]}, h^{[\sigma]} \mid \theta\right)\right]  \tag{32.13}\\
& =\sum_{\sigma} \sum_{m^{[\sigma]}, h^{[\sigma]}} P\left(m^{[\sigma]}, h^{[\sigma]} \mid x^{[\sigma]}, \theta^{(t)}\right) \ln P\left(m^{[\sigma]}, x^{[\sigma]}, h^{[\sigma]} \mid \theta\right)  \tag{32.14}\\
& =\sum_{\sigma} \sum_{m^{[\sigma],} h^{[\sigma]}} \frac{P\left(m^{[\sigma]}, h^{[\sigma]}, x^{[\sigma]} \mid \theta^{(t)}\right)}{P\left(x^{[\sigma]} \mid \theta^{(t)}\right)} \ln P\left(m^{[\sigma]}, x^{[\sigma]}, h^{[\sigma]} \mid \theta\right) \tag{32.15}
\end{align*}
$$

Once you find optimal parameters $\theta^{*}$ by recursing this $Q\left(\theta \mid \theta^{(t)}\right)$, you can evaluate numerically the $P(m)$ column of Table 32.2. In Table 32.2 , out of the 4 sub-rows for row 4 , choose the one with the highest probability. Similarly, out of the 2 sub-rows for row 5 , choose the one with the highest probability.

### 32.2 Imputation via MCMC

A simple and popular way to do inputation via MCMC is described in Ref.[37]. It goes as follows.

Let

$$
\begin{equation*}
\underline{H}[\sigma]=(\underline{h}[\sigma], \underline{m}[\sigma]) \tag{32.16}
\end{equation*}
$$

for $\sigma=0,1, \ldots, n s a m-1$. Initialize $\theta^{(0)}$ to a random value within the allowed ranges. Do the following 2 steps, for $t=0,1, \ldots, T-1$, where $T$ is large enough that $\theta^{(t)}$ has reached a steady value that is independent of $\theta^{(0)}$. To do the sampling, use a standard sampling technique such as Gibbs sampling.

- STEP 1: For $\sigma=0,1, \ldots, n s a m-1$, find a sample

$$
\begin{equation*}
\left(H^{[\sigma]}\right)^{(t+1)} \sim P\left(H^{[\sigma]} \mid x^{[\sigma]}, \theta^{(t)}\right) \tag{32.17a}
\end{equation*}
$$

- STEP 2: Find a sample

$$
\begin{equation*}
\theta^{(t+1)} \sim P^{(t+1)}(\theta) \tag{32.17b}
\end{equation*}
$$

where

$$
\begin{align*}
P^{(t+1)}(\theta) & =\mathcal{N}(!\theta) P\left(\vec{x}, \vec{H}^{(t+1)} \mid \theta\right)  \tag{32.17c}\\
& =\mathcal{N}(!\theta) \prod_{\sigma} P\left(x^{[\sigma]},\left(H^{[\sigma]}\right)^{(t+1)} \mid \theta\right) \tag{32.17d}
\end{align*}
$$

Fig 32.4 illustrates this two step recursive process using a bnet.

Figure 32.4: bnet illustrating Eqs. (32.17) for doing imputation via MCMC. The same node $\underline{\vec{x}}$ appears twice to make the graph clearer.

### 32.3 Multiple Imputations

Multiple imputations means calculating $\theta^{*}$ (i.e., the optimum $\theta$ ) and the concomitant dataset $\vec{x}^{*}, \vec{H}^{*}$, via any method (such as EM or MCMC), a large number of times, starting from different, randomly chosen $\theta^{(0)}$ initial parameters. Then calculating the average and the variance of $\theta^{*}, \vec{x}^{*}, \vec{H}^{*}$ and functions thereof.

## Chapter 33

## Monty Hall Problem

Figure 33.1: Monty Hall Problem.
Mr. Monty Hall, host of the game show "Lets Make a Deal", hides a car behind one of three doors and a goat behind each of the other two. The contestant picks Door No. 1, but before opening it, Mr. Hall opens Door No. 2 to reveal a goat. Should the contestant stick with No. 1 or switch to No. 3?

The Monty Hall problem can be modeled by the bnet Fig.33.1, where

- $\underline{c}=$ the door behind which the car actually is.
- $\underline{y}=$ the door opened by you (the contestant), on your first selection.
- $\underline{m}=$ the door opened by Monty (game host)

We label the doors $1,2,3$ so $S_{\underline{c}}=S_{\underline{y}}=S_{\underline{m}}=\{1,2,3\}$.
Node matrices printed in blue:

$$
\begin{gather*}
P(c)=\frac{1}{3} \text { for all } c  \tag{33.1}\\
P(y)=\frac{1}{3} \text { for all } y  \tag{33.2}\\
P(m \mid c, y)=\mathbb{1}(m \neq c)\left[\frac{1}{2} \mathbb{1}(y=c)+\mathbb{1}(y \neq c) \mathbb{1}(m \neq y)\right] \tag{33.3}
\end{gather*}
$$

It's easy to show that the above node probabilities imply that

$$
\begin{align*}
& P(c=1 \mid m=2, y=1)=\frac{1}{3}  \tag{33.4}\\
& P(c=3 \mid m=2, y=1)=\frac{2}{3} \tag{33.5}
\end{align*}
$$

So you are twice as likely to win if you switch your final selection to be the door which is neither your first choice nor Monty's choice.

The way I justify this to myself is: Monty gives you a piece of information. If you don't switch your choice, you are wasting that info, whereas if you switch, you are using the info.

## Chapter 34

## Naive Bayes

Figure 34.1: bnet for Naive Bayes with 4 features
Class node $\underline{c} \in S_{\underline{c}} .\left|S_{\underline{c}}\right|=n_{\underline{c}}=$ number of classes.
Feature nodes $\underline{x}_{i} \in S_{\underline{x}_{i}}$ for $i=0,1,2, \ldots, F-1 . F=$ number of features.
Define

$$
\begin{equation*}
x .=\left[x_{0}, x_{1}, \ldots, x_{F-1}\right] . \tag{34.1}
\end{equation*}
$$

For the bnet of Fig.34.1,

$$
\begin{equation*}
P(c, x .)=P(c) \prod_{i=0}^{F-1} P\left(x_{i} \mid c\right) \tag{34.2}
\end{equation*}
$$

Given $x$. values, find most likely class $c \in S_{\underline{c}}$.
Maximum a Posteriori (MAP) estimate:

$$
\begin{align*}
c^{*} & =\underset{c}{\operatorname{argmax}} P(c \mid x .)  \tag{34.3}\\
& =\underset{c}{\operatorname{argmax}} \frac{P(c, x .)}{P(x .)}  \tag{34.4}\\
& =\underset{c}{\operatorname{argmax}} P(c, x .) . \tag{34.5}
\end{align*}
$$

## Chapter 35

## Neural Networks

In this chapter, we discuss Neural Networks (NNs) of the feedforward kind, which is the most popular kind. In their plain, vanilla form, NNs only have deterministic nodes. But the nodes of a bnet can be deterministic too, because the TPM of a node can reduce to a delta function. Hence, NNs should be expressible as bnets. We will confirm this in this chapter.

Henceforth in this chapter, if we replace an index of an indexed quantity by a dot, it will mean the collection of the indexed quantity for all values of that index. For example, $x$. will mean the array of $x_{i}$ for all $i$.

Figure 35.1: Neural Network (feed forward) with 4 layers: input layer $\underline{x}$., 2 hidden layers $\underline{h}^{0}$., $\underline{h}^{1}$. and output layer $\underline{Y}$.

Consider Fig 35.1.
$\underline{x}_{i} \in\{0,1\}$ for $i=0,1,2, \ldots, n x-1$ is the input layer.
$\underline{h}_{i}^{\lambda} \in \mathbb{R}$ for $i=0,1,2, \ldots, n h(\lambda)-1$ is the $\lambda$-th hidden layer. $\lambda=0,1,2, \ldots, \Lambda-$
2. A $N N$ is said to be deep if $\Lambda>2$; i.e., if it has more than one hidden layer.
$\underline{Y}_{i} \in \mathbb{R}$ for $i=0,1,2, \ldots, n y-1$ is the output layer. We use a upper case y here because in the training phase, we will use pairs $(x .[\sigma], y .[\sigma])$ where $y_{i}[\sigma] \in\{0,1\}$
for $i=0,1, \ldots, n y-1 . Y=\hat{y}$ is an estimate of $y$. Note that lower case y is either 0 or 1 , but upper case y may be any real. Often, the activation functions are chosen so that $Y \in[0,1]$.

The number of nodes in each layer and the number of layers are arbitrary. Fig. 35.1 is fully connected (aka dense), meaning that every node of a layer is impinged arrow coming from every node of the preceding layer. Later on in this chapter, we will discuss non-dense layers.

Let $w_{i \mid j}^{\lambda}, b_{i}^{\lambda} \in \mathbb{R}$ be given, for $i \in[0, n h(\lambda))_{\mathbb{Z}}, j \in[0, n h(\lambda-1))_{\mathbb{Z}}$, and $\lambda \in$ $[0, \Lambda)_{\mathbb{Z}}$.

These are the TPMs, printed in blue, for the nodes of the bnet Fig 35.1;

$$
\begin{gather*}
P\left(x_{i} \mid x_{i-1}, x_{i-1}, \ldots, x_{0}\right)=\text { given }  \tag{35.1}\\
P\left(h_{i}^{\lambda} \mid h_{\cdot}^{\lambda-1}\right)=\delta\left(h_{i}^{\lambda}, \mathcal{A}_{i}^{\lambda}\left(\sum_{j} w_{i \mid j}^{\lambda} h_{j}^{\lambda-1}+b_{i}^{\lambda}\right)\right), \tag{35.2}
\end{gather*}
$$

where $P\left(h_{i}^{0} \mid h^{-1}\right)=P\left(h_{i}^{0} \mid x\right)$.

$$
\begin{equation*}
P\left(Y_{i} \mid h_{\cdot}^{\Lambda-2}\right)=\delta\left(Y_{i}, \mathcal{A}_{i}^{\Lambda-1}\left(\sum_{j} w_{i \mid j}^{\Lambda-1} h_{j}^{\Lambda-2}+b_{i}^{\Lambda-1}\right)\right) \tag{35.3}
\end{equation*}
$$

### 35.1 Activation Functions $\mathcal{A}_{i}^{\lambda}: \mathbb{R} \rightarrow \mathbb{R}$

Activation functions must be nonlinear.

- Step function (Perceptron)

$$
\begin{equation*}
\mathcal{A}(x)=\mathbb{1}(x>0) \tag{35.4}
\end{equation*}
$$

Zero for $x \leq 0$, one for $x>0$.

## - Sigmoid function

$$
\begin{equation*}
\mathcal{A}(x)=\frac{1}{1+e^{-x}}=\operatorname{sig}(x) \tag{35.5}
\end{equation*}
$$

Smooth, monotonically increasing function. $\operatorname{sig}(-\infty)=0, \operatorname{sig}(0)=0.5, \operatorname{sig}(\infty)=$ 1.

$$
\begin{align*}
\operatorname{sig}(x)+\operatorname{sig}(-x) & =\frac{1}{1+e^{-x}}+\frac{1}{1+e^{x}}  \tag{35.6}\\
& =\frac{2+e^{x}+e^{-x}}{2+e^{x}+e^{-x}}  \tag{35.7}\\
& =1 \tag{35.8}
\end{align*}
$$

## - Hyperbolic tangent

$$
\begin{equation*}
\mathcal{A}(x)=\tanh (x)=\frac{e^{x}-e^{-x}}{e^{x}+e^{-x}} \tag{35.9}
\end{equation*}
$$

Smooth, monotonically increasing function. $\tanh (-\infty)=-1, \tanh (0)=0$, $\tanh (\infty)=1$.
Odd function:

$$
\begin{equation*}
\tanh (-x)=-\tanh (x) \tag{35.10}
\end{equation*}
$$

Whereas $\operatorname{sig}(x) \in[0,1], \tanh (x) \in[-1,1]$.

## - ReLU (Rectified Linear Unit)

$$
\begin{equation*}
\mathcal{A}(x)=x \mathbb{1}(x>0)=\max (0, x) . \tag{35.11}
\end{equation*}
$$

Compare this to the step function.

## - Swish

$$
\begin{equation*}
\mathcal{A}(x)=x \operatorname{sig}(x) \tag{35.12}
\end{equation*}
$$

## - Softmax

$$
\begin{equation*}
\mathcal{A}\left(x_{i} \mid x .\right)=\frac{e^{x_{i}}}{\sum_{i} e^{x_{i}}} \tag{35.13}
\end{equation*}
$$

It's called softmax because if we approximate the exponentials, both in the numerator and denominator of Eq. (35.13), by the largest one, we get

$$
\begin{equation*}
\mathcal{A}\left(x_{i} \mid x .\right) \approx \mathbb{1}\left(x_{i}=\max _{k} x_{k}\right) . \tag{35.14}
\end{equation*}
$$

The softmax definition implies that the bnet nodes within a softmax layer are fully connected by arrows to form a "clique".

For 2 nodes $x_{0}, x_{1}$,

$$
\begin{align*}
\mathcal{A}\left(x_{0} \mid x .\right) & =\frac{e^{x_{0}}}{e^{x_{0}}+e^{x_{1}}}  \tag{35.15}\\
& =\operatorname{sig}\left(x_{0}-x_{1}\right),  \tag{35.16}\\
\mathcal{A}\left(x_{1} \mid x .\right) & =\operatorname{sig}\left(x_{1}-x_{0}\right) . \tag{35.17}
\end{align*}
$$

### 35.2 Weight optimization via supervised training and gradient descent

The bnet of Fig 35.1 is used for classification of a single data point $x$.. It assumes that the weights $w_{i \mid j}^{\lambda}, b_{i}^{\lambda}$ are given.

To find the optimum weights via supervised training and gradient descent, one uses the bnet Fig 35.2.

In Fig 35.2 , the nodes in Fig 35.1 become sampling space vectors. For example, $\underline{x}$. becomes $\underline{\vec{x}}$., where the components of $\underline{\vec{x}}$. in sampling space are $\underline{x} \cdot[\sigma] \in\{0,1\}^{n x}$ for $\sigma=0,1, \ldots, n \operatorname{sam}(\vec{x})-1$.
$\operatorname{nsam}(\vec{x})$ is the number of samples used to calculate the gradient during each stage (aka iteration) of Fig. 35.2 . We will also refer to $n \operatorname{sam}(\vec{x})$ as the mini-batch size. A mini-batch is a subset of the training dataset.

To train a bnet with a data set (d-set), the standard procedure is to split the d-set into 3 parts:

1. training d-set,
2. testing1 d-set, for tuning of hyperparameters like $n \operatorname{sam}(\vec{x}), \Lambda$, and $n u n h(i)$ for each $i$.
3. testing2 d-set, for measuring how well the model tuned with the testing1 d-set performs.

The training d-set is itself split into mini-batches. An epoch is a pass through all the training d-set.

Define

$$
\begin{equation*}
W_{i \mid j}^{\lambda}=\left[w_{i \mid j}^{\lambda}, b_{i}^{\lambda}\right] . \tag{35.18}
\end{equation*}
$$

These are the TPMs, printed in blue, for the nodes of the bnet Fig. 35.2,

$$
\begin{gather*}
P(x \cdot[\sigma])=\text { given } .  \tag{35.19}\\
P(y \cdot[\sigma] \mid x \cdot[\sigma])=\text { given } .  \tag{35.20}\\
P\left(h_{i}^{\lambda}[\sigma] \mid h_{\cdot}^{\lambda-1}[\sigma]\right)=\delta\left(h_{i}^{\lambda}[\sigma], \mathcal{A}_{i}^{\lambda}\left(\sum_{j} w_{i \mid j}^{\lambda} h_{j}^{\lambda-1}[\sigma]+b_{i}^{\lambda}\right)\right)  \tag{35.21}\\
P\left(Y_{i}[\sigma] \mid h_{\cdot}^{\Lambda-2}[\sigma]\right)=\delta\left(Y_{i}[\sigma], \mathcal{A}_{i}^{\Lambda-1}\left(\sum_{j} w_{i \mid j}^{\Lambda-1} h_{j}^{\Lambda-2}[\sigma]+b_{i}^{\Lambda-1}\right)\right) \tag{35.22}
\end{gather*}
$$

Figure 35.2: bnet for finding optimum weights of the bnet Fig 35.1 via supervised training and gradient descent.

$$
\begin{equation*}
P\left(W_{\mathrm{j} .}\right)=\text { given } \tag{35.23}
\end{equation*}
$$

The first time it is used, $W_{\text {.. }}$ is arbitrary. After the first time, it is determined by previous stage.

$$
\begin{gather*}
P\left(W_{.| |}^{\lambda} \mid W_{\cdot \mid}\right)=\delta\left(W_{. \mid .}^{\lambda},\left(W_{. \mid .}\right)^{\lambda}\right)  \tag{35.24}\\
P(\mathcal{E} \mid \vec{y} ., \vec{Y} .)=\frac{1}{n \operatorname{sam}(\vec{x})} \sum_{\sigma} \sum_{i} d\left(y_{i}[\sigma], Y_{i}[\sigma]\right), \tag{35.25}
\end{gather*}
$$

where

$$
\begin{equation*}
d(y, Y)=|y-Y|^{2} . \tag{35.26}
\end{equation*}
$$

If $y, Y \in[0,1]$, one can use this instead

$$
\begin{gather*}
d(y, Y)=X E(y \rightarrow Y)=-y \ln Y-(1-y) \ln (1-Y) .  \tag{35.27}\\
P\left(\left(W^{\prime}\right)_{i \mid j}^{\lambda} \mid \mathcal{E}, W_{\cdot j}\right)=\delta\left(\left(W^{\prime}\right)_{i \mid j}^{\lambda}, W_{i \mid j}^{\lambda}-\eta \partial_{W_{i \mid j}^{\lambda}} \mathcal{E}\right) \tag{35.28}
\end{gather*}
$$

$\eta>0$ is called the learning rate. This method of minimizing the error $\mathcal{E}$ is called gradient descent. $W^{\prime}-W=\Delta W=-\eta \partial_{W} \mathcal{E}$ so $\Delta \mathcal{E}=\frac{-1}{\eta}(\Delta W)^{2}<0$.

### 35.3 Non-dense layers

The TPM for a non-dense layer is of the form:

$$
\begin{equation*}
P\left(h_{i}^{\lambda}[\sigma] \mid h^{\lambda-1}[\sigma]\right)=\delta\left(h_{i}^{\lambda}[\sigma], H_{i}^{\lambda}[\sigma]\right), \tag{35.29}
\end{equation*}
$$

where $H_{i}^{\lambda}[\sigma]$ will be specified below for each type of non-dense layer.

## - Dropout Layer

The dropout layer was invented in Ref.[35]. To dropout nodes from a fixed layer $\lambda$ : For all $i$ of layer $\lambda$, define a new node $\underline{r}_{i}^{\lambda}$ with an arrow $\underline{r}_{i}^{\lambda} \rightarrow \underline{h}_{i}^{\lambda}$. For $r \in\{0,1\}$, and some $p \in(0,1)$, define

$$
\begin{equation*}
P\left(r_{i}^{\lambda}=r\right)=[p]^{r}[1-p]^{1-r} \text { (Bernouilli dist.) . } \tag{35.30}
\end{equation*}
$$

Now one has

$$
\begin{equation*}
P\left(h_{i}^{\lambda}[\sigma] \mid h_{.}^{\lambda-1}[\sigma], r_{i}^{\lambda}\right)=\delta\left(h_{i}^{\lambda}[\sigma], H_{i}^{\lambda}[\sigma]\right), \tag{35.31}
\end{equation*}
$$

where

$$
\begin{equation*}
H_{i}^{\lambda}[\sigma]=\mathcal{A}_{i}^{\lambda}\left(r_{i}^{\lambda} \sum_{j} w_{i \mid j}^{\lambda} h_{j}^{\lambda-1}[\sigma]+b_{i}^{\lambda}\right) . \tag{35.32}
\end{equation*}
$$

This reduces ovefitting. Overfitting might occur if the weights follow too closely several similar minibatches. This dropout procedure adds a random component to each minibatch making groups of similar minibatches less likely.
The random $\underline{r}_{i}^{\lambda}$ nodes that induce dropout are only used in the training bnet Fig. 35.2 , not in the classification bnet Fig. 35.1. We prefer to remove the $\underline{r}_{i}^{\lambda}$ stochasticity from classification and for Fig 35.1 to act as an average over sampling space of Fig 35.2. Therefore, if weights $w_{i j j}^{\lambda}$ are obtained for a dropout layer $\lambda$ in Fig. 35.2 , then that layer is used in Fig. 35.1 with no $\underline{r}_{i}^{\lambda}$ nodes but with weights $\left\langle r_{i}^{\lambda}\right\rangle w_{i \mid j}^{\lambda}=p w_{i \mid j}^{\lambda}$.
Note that dropout adds non-deterministic nodes to a NN, which in their vanilla form only have deterministic nodes.

## - Convolutional Layer

- 1-dim

Filter function $\mathcal{F}:\{0,1, \ldots, n f-1\} \rightarrow \mathbb{R}$.
$\sigma=$ stride length

For $i \in\{0,1, \ldots, n h(\lambda)-1\}$, let

$$
\begin{equation*}
H_{i}^{\lambda}[\sigma]=\sum_{j=0}^{n f-1} h_{j+i \sigma}^{\lambda-1}[\sigma] \mathcal{F}(j) . \tag{35.33}
\end{equation*}
$$

For the indices not to go out of bounds in Eq. 35.33 ), we must have

$$
\begin{equation*}
n h(\lambda-1)-1=n f-1+(n h(\lambda)-1) \sigma \tag{35.34}
\end{equation*}
$$

so

$$
\begin{equation*}
n h(\lambda)=\frac{1}{\sigma}[n h(\lambda-1)-n f]+1 . \tag{35.35}
\end{equation*}
$$

- 2-dim
$h_{i}^{\lambda}[\sigma]$ becomes $h_{(i, j)}^{\lambda}[\sigma]$. Do 1-dim convolution along both $i$ and $j$ axes.

## - Pooling Layers (MaxPool, AvgPool)

Here each node $i$ of layer $\lambda$ is impinged by arrows from a subset $\operatorname{Pool}(i)$ of the set of all nodes of the previous layer $\lambda-1$. Partition set $\{0,, 1, \ldots, n h(\lambda-$ 1) -1$\}$ into $n h(\lambda)$ mutually disjoint, nonempty sets called $\operatorname{Pool}(i)$, where $i \in$ $\{0,1, \ldots, n h(\lambda)-1\}$.

- AvgPool

$$
\begin{equation*}
H_{i}^{\lambda}[\sigma]=\frac{1}{|\operatorname{Pool}(i)|} \sum_{j \in \operatorname{Pool}(i)} h_{j}^{\lambda-1}[\sigma] \tag{35.36}
\end{equation*}
$$

- MaxPool

$$
\begin{equation*}
H_{i}^{\lambda}[\sigma]=\max _{j \in \operatorname{Pool}(i)} h_{j}^{\lambda-1}[\sigma] \tag{35.37}
\end{equation*}
$$

### 35.4 Autoencoder NN

If the sequence

$$
\begin{equation*}
n x, n h(0), n h(1), \ldots, n h(\Lambda-2), n y \tag{35.38}
\end{equation*}
$$

first decreases monotonically up to layer $\lambda_{\text {min }}$, then increases monotonically until $n y=n x$, then the NN is called an autoencoder NN. Autoencoders are useful for unsupervised learning and feature reduction. In this case, $Y$ estimates $x$. The layers before layer $\lambda_{\min }$ are called the encoder, and those after $\lambda_{\min }$ are called the decoder. Layer $\lambda_{\text {min }}$ is called the code.

## Chapter 36

## Noisy-OR gate

The Noisy-OR gate was first proposed by Judea Pearl in his 1988 book Ref.[25].

Figure 36.1: Noisy-OR gate $\underline{y} \in\{0,1\}$ with $n=3$, Boolean inputs $\left(\underline{x}_{i}\right)_{i=0,1,2}$ and parameters $\underline{\lambda},(\underline{\pi})_{i=0,1,2}$.

Let
$\underline{\lambda} \in[0,1]=$ gate leakage.
$y \in\{0,1\}=$ gate output
$\underline{x}^{n}=\left(\underline{x}_{i}\right)_{i=0,1, \ldots, n-1}$, where $\underline{x}_{i} \in\{0,1\}$ are gate inputs.
$\underline{\pi}^{n}=\left(\underline{\pi}_{i}\right)_{i=0,1, \ldots, n-1}$, where $\underline{\pi}_{i} \in[0,1]$ are gate parameters.
The TPM, printed in blue, for the Noisy-OR gate $\underline{y}$ shown in Fig. 36.1, is

$$
\begin{gather*}
P\left(y=1 \mid x^{n}, \lambda, \pi^{n}\right)=1-(1-\lambda) \prod_{i}\left[1-\pi_{i} x_{i}\right]  \tag{36.1}\\
P\left(y=0 \mid x^{n}, \lambda, \pi^{n}\right)=1-P\left(y=1 \mid x^{n}, \lambda, \pi^{n}\right) \tag{36.2}
\end{gather*}
$$

Note that if $\lambda=0$ and $\pi_{i}=1$ for all $i$, then this becomes a deterministic OR-gate. Indeed,

$$
\begin{equation*}
P\left(y=1 \mid x^{n}, \lambda=0, \pi^{n}=1^{n}\right)=1-\prod_{i}\left[1-x_{i}\right]=\vee_{i=0}^{n-1} x_{i}, \tag{36.3}
\end{equation*}
$$

$$
\begin{equation*}
P\left(y \mid x^{n}, \lambda=0, \pi^{n}=1^{n}\right)=\delta\left(y, \vee_{i=0}^{n-1} x_{i}\right) \tag{36.4}
\end{equation*}
$$

### 36.13 ways to interpret the parameters $\pi_{i}$

1. Note that if $\lambda=0$ and $x^{n}$ is one hot (i.e., $x^{n}=e_{i}^{n}$, where $e_{i}^{n}$ is the vector with all components zero except for the $i$-th component which equals 1 ), then

$$
\begin{equation*}
P\left(y=1 \mid x^{n}=e_{i}^{n}, \lambda=0, \pi^{n}\right)=1-\left[1-\pi_{i}\right]=\pi_{i} . \tag{36.5}
\end{equation*}
$$

This gives an interpretation to the parameters $\pi_{i}$.

Figure 36.2: Fig 36.1 after replacing parameters $\left(\underline{\pi}_{i}\right)_{i=0,1,2}$ by hidden nodes $\left(\underline{h}_{i}\right)_{i=0,1,2}$.
2. Another way of interpreting the parameters $\pi_{i}$ is to associate each of them with a hidden variable $\underline{h}_{i} \in\{0,1\}$ whose average equals $\pi_{i}$. More precisely, consider Fig 36.2.

Let $\underline{x}_{i}, \underline{h}_{i}, \underline{A}_{i}, \underline{y} \in\{0,1\}$.
The TPMs, printed in blue, for the nodes of the bnet Fig 36.2, are as follows:

$$
\begin{gather*}
P\left(h_{i}\right)=\pi_{i} \delta\left(h_{i}, 1\right)+\left(1-\pi_{i}\right) \delta\left(h_{i}, 0\right)  \tag{36.6}\\
P\left(A_{i} \mid h_{i}, x_{i}\right)=\delta\left(A_{i}, h_{i} \wedge x_{i}\right)=\delta\left(A_{i}, h_{i} x_{i}\right) \tag{36.7}
\end{gather*}
$$

$$
\begin{align*}
P\left(y=1 \mid A^{n}\right) & =1-(1-\lambda) \wedge_{i=0}^{n-1} \bar{A}_{i}  \tag{36.8}\\
& =1-(1-\lambda) \prod_{i}\left(1-A_{i}\right) \tag{36.9}
\end{align*}
$$

$$
\begin{equation*}
P\left(y=0 \mid A^{n}\right)=1-P\left(y=1 \mid A^{n}\right) \tag{36.10}
\end{equation*}
$$

Note that

$$
\begin{align*}
P\left(y=1 \mid x^{n}, \lambda\right) & =\sum_{h^{n}} \sum_{A^{n}}\left[1-(1-\lambda) \prod_{i}\left(1-A_{i}\right)\right]\left[\prod_{i} \delta\left(A_{i}, h_{i} x_{i}\right)\right] P\left(h^{n}\right)  \tag{36.11}\\
& =E_{\underline{h}^{n}}\left[\left[1-(1-\lambda) \prod_{i}\left(1-h_{i} x_{i}\right)\right] .\right. \tag{36.12}
\end{align*}
$$

But

$$
\begin{equation*}
E_{\underline{h}_{i}}\left[h_{i} x_{i}\right]=\sum_{h_{i}=0,1} P\left(h_{i}\right) h_{i} x_{i}=\pi_{i} x_{i} \tag{36.13}
\end{equation*}
$$

so

$$
\begin{equation*}
P\left(y=1 \mid x^{n}, \lambda\right)=1-(1-\lambda) \prod_{i}\left(1-\pi_{i} x_{i}\right) . \tag{36.14}
\end{equation*}
$$

Figure 36.3: Fig 36.2 after replacing the hidden nodes $\left(\underline{h}_{i}\right)_{i=0,1,2}$ by vectors of samples $\left(\overrightarrow{\underline{h}}_{i}\right)_{i=0,1,2}$.
3. Another way to interpret the parameters $\pi_{i}$ is to associate each of them with a vector of samples $\overrightarrow{\underline{h}}_{i}$ whose average is $\pi_{i}$. More precisely, consider Fig 36.3.
Suppose $\underline{h}_{i} \in\{0,1\}$ and define

$$
\begin{equation*}
P_{\underline{h}_{i}}\left(h_{i}\right)=\pi_{i} \delta\left(h_{i}, 1\right)+\left(1-\pi_{i}\right) \delta\left(h_{i}, 0\right) . \tag{36.15}
\end{equation*}
$$

Suppose $\overrightarrow{\underline{h}}_{i}=\left(\underline{h}_{i}[\sigma]\right)_{s=0,1, \ldots, n s a m-1}$ and the Boolean samples $\underline{h}_{i}[\sigma] \in\{0,1\}$ are i.i.d. with $\underline{h}_{i}[\sigma] \sim P_{\underline{h}_{i}}$ for all $\sigma$.

Note that for each $i$, an estimate $\hat{P}_{\underline{h}_{i}}\left(h_{i}\right)$ of $P_{\underline{\underline{h}}_{i}}\left(h_{i}\right)$ can be obtained from the vector of samples $\overrightarrow{\underline{h}}_{i}$ as follows:

$$
\begin{equation*}
\hat{P}_{\underline{h}_{i}}\left(h_{i}\right)=\frac{1}{n s a m} \sum_{\sigma=0}^{n s a m-1} \mathbb{1}\left(h_{i}[\sigma]=h_{i}\right) . \tag{36.16}
\end{equation*}
$$

Let $\underline{x}_{i}, \underline{h}_{i}[\sigma], \underline{A}_{i}, \underline{y} \in\{0,1\}$.
The TPMs, printed in blue, for the nodes of the bnet Fig 36.3, are as follows:

$$
\begin{align*}
& P\left(\vec{h}_{i}\right)=\prod_{\sigma=0}^{n s a m-1} P_{\underline{h}}\left(h_{i}[\sigma]\right)  \tag{36.17}\\
& P\left(A_{i} \mid \vec{h}_{i}, x_{i}\right)=\delta\left(A_{i}, \frac{1}{n s a m} \sum_{\sigma} h_{i}[\sigma] \wedge x_{i}\right)  \tag{36.18}\\
&=\delta\left(A_{i}, \pi_{i} x_{i}\right)  \tag{36.19}\\
& P\left(y=1 \mid A^{n}\right)=1-(1-\lambda) \wedge_{i=0}^{n-1} \bar{A}_{i}  \tag{36.20}\\
&=1-(1-\lambda) \prod_{i}\left(1-A_{i}\right)  \tag{36.21}\\
& P\left(y=0 \mid A^{n}\right)=1-P\left(y=1 \mid A^{n}\right) \tag{36.22}
\end{align*}
$$

Note that

$$
\begin{align*}
P\left(y=1 \mid x^{n}, \lambda, \vec{h}^{n}\right) & =\sum_{A^{n}}\left[1-(1-\lambda) \prod_{i}\left(1-A_{i}\right)\right] \prod_{i} \delta\left(A_{i}, \pi_{i} x_{i}\right)  \tag{36.23}\\
& =1-(1-\lambda) \prod_{i}\left(1-\pi_{i} x_{i}\right) \tag{36.24}
\end{align*}
$$

## Chapter 37

## Non-negative Matrix Factorization

Based on Ref. 74].
Given matrix $V$, factor it into product of two matrices

$$
\begin{equation*}
V=W H \tag{37.1}
\end{equation*}
$$

where all 3 matrices have non-negative entries.
$V \in \mathbb{R}_{\geq 0}^{n v \times n a}$ : visible info matrix
$W \in \mathbb{R}_{\geq 0}^{n v \times n h}$ : weight info matrix
$H \in \mathbb{R}_{\geq 0}^{n h \times n a}$ : hidden info matrix
Usually, $n v>n h<n a$ so compression of information (aka dimensional reduction, clustering)

### 37.1 Bnet interpretation

Express node $\underline{v}$ as a chain of two nodes.

$$
\underline{v} \leftarrow \underline{a} \quad=\quad \underline{w} \leftarrow \underline{h} \leftarrow \underline{a}
$$

Figure 37.1: B net interpretation of non-negative matrix factorization.

Node TPMs, printed in blue, for Fig 37.1.

$$
\begin{gather*}
P(\underline{v}=w \mid a)=\frac{V_{w, a}}{\sum_{w} V_{w, a}}  \tag{37.2}\\
P(w \mid h)=\frac{W_{w, h}}{\sum_{w} W_{w, h}} \tag{37.3}
\end{gather*}
$$

$$
\begin{equation*}
P(h \mid a)=\frac{\sum_{w} W_{w, h}}{\sum_{w} V_{w, a}} H_{h, a} \tag{37.4}
\end{equation*}
$$

### 37.2 Simplest recursive algorithm

Initialize: Choose $n h$. Choose $W^{(0)}$ and $H^{(0)}$ that have non-negative entries.
Update: For $n=0,1, \ldots$, do

$$
\begin{equation*}
H_{i, j}^{(n+1)} \leftarrow H_{i, j}^{(n)} \frac{\left[\left(W^{(n)}\right)^{T} V\right]_{i, j}}{[\left(W^{(n)}\right)^{T} \underbrace{W^{(n)} H^{(n)}}_{\approx V}]_{i, j}} \tag{37.5}
\end{equation*}
$$

and

$$
\begin{equation*}
W_{i, j}^{(n+1)} \leftarrow W_{i, j}^{(n)} \frac{\left[V\left(H^{(n+1)}\right)^{T}\right]_{i, j}}{[\underbrace{W^{(n)} H^{(n+1)}}_{\approx V}\left(H^{(n+1)}\right)^{T}]_{i, j}} . \tag{37.6}
\end{equation*}
$$

After each step, record error defined by

$$
\begin{equation*}
\mathcal{E}^{(n)}=\left\|V-W^{(n)} H^{(n)}\right\|_{2} . \tag{37.7}
\end{equation*}
$$

Using 2-norm, aka Frobenius matrix norm. Continue until reach acceptable error.
Can also use Kullback-Lieber divergence for error:

$$
\begin{equation*}
\mathcal{E}=\sum_{a} P(a) D_{K L}\left(P(\underline{v}=w \mid a) \| \sum_{h} P(w \mid h) P(h \mid a)\right), \tag{37.8}
\end{equation*}
$$

for some arbitrary choice of prior $P(a)$. For example, can choose $P(a)$ uniform.

## Chapter 38

## Observational Equivalence of DAGs

This chapter is based on Chapter 1 of Ref. [26] and on a blog post by Bruno Gonçalves (Ref.[8]).

A probability distribution $P$ is compatible with a DAG $G$ if $P$ and $G$ have the same random variables, and they can be combined to form a bnet without contradictions; i.e., one can calculate all the TPMs from $P$ and multiply them together to obtain $P$ again. Let

$$
\begin{equation*}
\mathcal{P}(G)=\{P: P \text { is compatible with } G\} . \tag{38.1}
\end{equation*}
$$

Two DAGs $G$ and $G^{\prime}$ are observationally equivalent (OE) if $\mathcal{P}(G)=$ $\mathcal{P}\left(G^{\prime}\right)$. Hence, any total probability distribution that is compatible with one of them is compatible with the other. For example, $\underline{a} \rightarrow \underline{b}$ and $\underline{a} \leftarrow \underline{b}$ are OE because

$$
\begin{equation*}
P(a \mid b) P(b)=P(a, b)=P(b \mid a) P(a) . \tag{38.2}
\end{equation*}
$$

We'll say two bnets are OE if their DAGs are OE.
Two DAGs $G$ and $G^{\prime}$ are d-separation equivalent if $D S(G)=D S\left(G^{\prime}\right)$. See Chapter 14 for definition of $D S(G)$.

Claim 24 Two DAGs are OE iff their DAGs are d-separation equivalent.
The skeleton of a DAG is its undelying undirected graph.
A v-structure in a DAG consists of two arrows converging to a node and such that their tails are not connected by a third arrow. Fig 38.1 shows in red all the v-structures of a particular DAG.

Claim 25 Observational Equivalence Theorem (by Verma and Pearl, 1990)
Two DAGs are OE iff they have the same skeletons and the same v-structures.

Figure 38.1: Example showing in red all v-structures of a particular DAG.

Figure 38.2: These 3 DAGs are observational equivalent (OE).

### 38.1 Examples

The 3 DAGs in Fig. 38.2 are OE. They form an equivalence class of OE DAGs that represent the same probability distribution. This equivalence class of DAGs can be represented by the partially directed graph Fig. 38.3 . These 3 DAGs can be proven to be OE in the following 3 ways:

1. Write the generic probability distributions represented by the 3 DAGs, and show that they are equal, as we did in Eq. 38.2 . That is the low brow way of proving OE.
2. Use d-separation (see Chapter 14). Consider DAG (a) first. Rename the nodes as $\underline{\tau}_{j}$ with $j=1,2, \ldots$ so that the names are in topological order (i.e., so that the parents of $\underline{\tau}_{j}$ have indices that are smaller than $j$ ). The node names $\underline{x}_{j}$ of DAG (a) are already in topologigal order, so we skip this step for DAG (a).

## (c)

Figure 38.3: This partially directed graph represents the 3 DAGs in Fig 38.2 .
Now write down its total probability distribution and notice which parents of a fully connected DAG were omitted.

$$
\begin{equation*}
P\left(x_{1}, x_{2}, x_{3}, x_{4}, x_{5}\right)=\underbrace{P\left(x_{5} \mid x_{4}\right)}_{x_{3}, x_{2}, x_{1} \text { omitted }} \underbrace{P\left(x_{4} \mid x_{3}, x_{2}\right)}_{x_{1} \text { omitted }} \underbrace{P\left(x_{3} \mid x_{1}\right)}_{x_{2} \text { omitted }} P\left(x_{2} \mid x_{1}\right) P\left(x_{1}\right) \tag{38.3}
\end{equation*}
$$

The observations of which parents were omitted can be stated in d-separation lingo as the following 3 orthogonality relations $\backslash^{1}$

$$
\begin{array}{r|l}
\underline{x}_{3} \perp_{P} \underline{x}_{2} & \underline{x}_{1} \\
\underline{x}_{4} \perp_{P} \underline{x}_{1} & \underline{x}_{2}, \underline{x}_{3} \\
\underline{x}_{5} \perp_{P}\left(\underline{x}_{1}, \underline{x}_{2}, \underline{x}_{3}\right) & \underline{x}_{4} . \tag{38.4c}
\end{array}
$$

Going through the same procedure for the other 2 DAGs yields, for each of them, an equivalent set of 3 orthogonality equations ${ }^{2}$
This is enough to conclude that the 3 DAGs of Fig 38.2 are OE.
Note that Eqs.(38.4) encompass all that there is to say about the observability of DAG (a). These 3 equations can be checked empirically to assess how well

[^19]the DAG fits the data. For example, one can do OLS (ordinary least squares) regression $x_{5} \sim x_{1}+x_{2}+x_{3}+x_{4}$ on the data, i.e., try to fit $x_{5}=\beta_{0}+\sum_{i=1}^{4} \beta_{i} x_{i}$ to the data, and find that, to a good approximation, $\beta_{1}=\beta_{2}=\beta_{3}=0$.
3. Use the OE Theorem. All three DAGs have the same skeleton, and the same single v-structure $\underline{x}_{2} \rightarrow \underline{x}_{4} \leftarrow \underline{x}_{3}$.

## Chapter 39

## Potential Outcomes

This chapter is based on Ref.[3], a book by Stephen Cunningham entitled "Causal inference: the mixtape".

The theory of potential outcomes (PO) was for the most part invented in a seminal 1974 paper by Donald B. Rubin. Rubin has also made important extensions to PO theory since 1974. However, he refuses to use Pearl's causal DAGs to discuss PO theory. Pearl has shown that PO theory can be substantially clarified and extended by using the language of causal DAGs. The d-separation theorem that we discuss in Chapter 14 is especially useful in this regard.

In this chapter, we stress the connection of PO theory to bnets, and, in particular, to the do and imagine operators defined in Chapter 9. Hence, before reading this chapter, the reader is expected to have at least skimmed Chapter 9, so that he/she understands the definition of do and imagine operators.

| $\sigma$ | $\underline{d}^{\sigma}$ | $\underline{y}^{\sigma}$ | $\underline{y}^{\sigma}(0)$ | $\underline{y}^{\sigma}(1)$ |
| :--- | :--- | :--- | :--- | :--- |

| Ben | 1 | 5 | $\cdot$ | 5 |
| Chad | 1 | 16 | $\cdot$ | 16 |
| Daniel | 1 | 3 | . | 3 |

Table 39.1: PO dataset describing whether individual $\sigma$ took a treatment dose ( $d^{\sigma}=$ $1)$ or didn't $\left(d^{\sigma}=0\right)$. The treatment outcome is measured by the real number $y^{\sigma}$.

Suppose a population of individuals $\sigma=0,1,2, \ldots, n s a m-1$ is given $\left(d^{\sigma}=1\right)$ or not given $\left(d^{\sigma}=0\right)$ a treatment discrete drug dose $d^{\sigma}$, and that the treatment outcome (i.e., response) is measured by a real number $y^{\sigma}$. Table 39.1 gives a possible PO dataset for this scenario. As you can see from that table, each individual either takes a drug dose or doesn't, but not both. PO theory can be
viewed as a missing data (MD) problem. MD problems are discussed in Chapter 32. However, the PO MD problem is much more specialized than the generic MD problems discussed in Chapter 32. In the PO MD problem, we can fill in the blank cells by matching each individual that took the drug with another similar individual that didn't. We will have much more to say about this matching strategy later in this chapter.

One can define similar individuals as individuals that have the same value for $n x$ features $x^{\sigma}=\left(x_{i}^{\sigma}\right)_{i=0,1, \ldots, n x-1}$. One can add to Table 39.1 $n x$ extra columns giving the value of the feature vector $x^{\sigma}$ for each individual. Members of a population with the same $x^{\sigma}$ are referred to as a subpopulation or stratum (ie., layer).

In a randomized clinical trial (RCT) ${ }^{1}$, the effect of the variable $x^{\sigma}$ on the value of $d^{\sigma}$ is eliminated by randomizing the population and therefore making the effect of $x^{\sigma}$ average out to zero. However, there are many situations in which carrying out an RCT is not possible. PO theory is a way of predicting the result of an RCT in situations where doing a real RCT is not physically possible.

In this chapter, $x^{\sigma}$ will be called the confounders. Implicit throughout this chapter is the assumption that there are no unmeasured confounders. Because if there are some unmeasured confounders, those can send secret messages that influence the value that $d^{\sigma}$ takes. This would ruin the predictions of someone trying to predict the results of an RCT without being privy to those secret messages. When there are some unmeasured confounders, it might still be possible to predict the effect of an RCT. This might be possible using instrumental variables. See Chapter 23 for a discussion of instrumental variables.

## $39.1 G$ and $G_{d e n}$, bnets, the starting point bnets

In this chapter, we will abbreviate $\underline{X}[\sigma]=\underline{X}^{\sigma}$ for $X \in\{d, x, y\}$ and for $\sigma=$ $\{0,1,2, \ldots$, nsam -1$\}$.

For each individual (aka unit, sample) $\sigma=0,1,2, \ldots n s a m-1$, let:
$\underline{d}^{\sigma} \in\{0,1\}$ : treatment discrete drug dose, 1 if treated and 0 if untreated
$\underline{y}^{\sigma} \in \mathbb{R}$ : treatment potential outcome
$\underline{\bar{x}}^{\sigma}:$ column vector of treatment confounders (aka covariates, because they are often used as covariates (i.e., independent variables) in linear regression.)

Consider bnets $G$ and $G_{d e n}$ in Fig.39.1. $G$ reflects the language used in Ref.[3] to discuss PO theory. And $G_{d e n}$ reflects the language that Judea Pearl prefers to use to discuss PO theory. Both languages are equivalent. To go from one language to the other, one need only perform the following swaps, where $\underline{u}$ is the external noise of the DEN bnet.

$$
\underline{X}^{\sigma} \leftrightarrow \underline{X}(\underline{u}) \text { for } X \in\{d, x, y\} .
$$

[^20]

Figure 39.1: Bnets $G$ and $G_{d e n}$ are our starting point in discussing PO theory. $G$ is for a single individual $\sigma$ of the population. Bnet $G_{d e n}$ is the DEN counterpart to $G$. DEN (Deterministic with External Noise) bnets are discussed in Chapter 27.

$$
\begin{aligned}
& P(\sigma)=\frac{1}{\text { nsam }} \leftrightarrow P(u) \\
& \sum_{\sigma} P(\sigma)(\cdot) \leftrightarrow \sum_{u} P(u)(\cdot)
\end{aligned}
$$

The TPMs, printed in blue, for the bnet $G$ in Fig 39.1, are as follows:

$$
\begin{gather*}
P\left(x^{\sigma}\right)=P_{\underline{x}}\left(x^{\sigma}\right)  \tag{39.1}\\
P\left(d^{\sigma} \mid x^{\sigma}\right)=P_{\underline{d} \mid \underline{x}}\left(d^{\sigma} \mid x^{\sigma}\right)  \tag{39.2}\\
P\left(y^{\sigma} \mid x^{\sigma}, d^{\sigma}\right)=P_{\underline{y} \underline{\mid x, d}}\left(y^{\sigma} \mid x^{\sigma}, d^{\sigma}\right) \tag{39.3}
\end{gather*}
$$

Now let:
$\underline{d} \in\{0,1\}$ : treatment discrete drug dose, 1 if treated and 0 if untreated $\underline{y} \in \mathbb{R}$ : treatment potential outcome
$\underline{x}$ : column vector of treatment confounders (aka covariates)
$\underline{u}=\left(\underline{u_{d}}, \underline{u_{x}}, \underline{u}_{\underline{y}}\right)$ : external noise
The TPMs, printed in blue, for the bnet $G_{d e n}$ in Fig 39.1, are as follows:

$$
\begin{gather*}
P\left(x \mid u_{\underline{x}}\right)=\mathbb{1}\left(x=u_{\underline{x}}\right)  \tag{39.4}\\
P\left(d \mid x, u_{\underline{d}}\right)=\mathbb{1}\left(d=f_{\underline{d}}\left(x, u_{\underline{d}}\right)\right)  \tag{39.5}\\
P\left(y \mid d, x, u_{\underline{y}}\right)=\mathbb{1}\left(y=f_{\underline{y}}\left(d, x, u_{\underline{y}}\right)\right) \tag{39.6}
\end{gather*}
$$

If we linearize $f_{\underline{y}}$ in Eq. 39.6), we get

$$
\begin{equation*}
\underline{y}=\delta \underline{d}+\beta \underline{x}+\underline{u}_{\underline{y}}, \tag{39.7}
\end{equation*}
$$

where $\delta, \beta \in \mathbb{R}$. Assuming that $\underline{x}, \underline{y} \in \mathbb{R}$ and $\underline{d} \in\{0,1\}$, Eq. (39.7) can be plotted. The resulting plot is given in Fig 39.2. This plot is a very special case of the PO problem, but it gives a crude idea of the "effects" $\delta=y(1)-y(0)$ that PO theory gives estimates for. Any individual participating in the experiment experiences either $y(1)$ or $y(0)$, but not both.

Figure 39.2: Plot of Eq. 39.7

## $39.2 G_{d o+}$ bnet

Figure 39.3: Bnet $G_{d o}=\rho_{\underline{d}^{\sigma}}\left(\tilde{d}^{\sigma}\right) G$ is obtained by applying the do operator to node $\underline{d}^{\sigma}$ of bnet $G$. Bnet $G_{d o+}$ is obtained by adding a prior probability distribution $P\left(\tilde{d}^{\sigma}\right)$ to node $\rho \underline{d}^{\sigma}$ of bnet $G_{d o}$.

Fig 39.3 shows how bnet $G_{d o}$ is obtained by applying the do operator to bnet $G$, and how bnet $G_{d o+}$ is obtained by adding a prior probability distribution to one
of the nodes of $G_{d o}$. In bnet $G_{d o}$, node $\underline{d}^{\sigma}$ has been stripped of all outside influences and fixed to a specific state $\tilde{d}^{\sigma}$. This is what an RCT does.

The TPMs, printed in blue, for the bnets $G_{d o}$ and $G_{d o+}$, are as follows. Note that the TPMs for bnets $G_{d o}$ and $G_{d o+}$ are defined in terms of the TPMs of bnet $G$.

$$
\begin{gather*}
P\left(x^{\sigma}\right)=P_{\underline{x}}\left(x^{\sigma}\right)  \tag{39.8}\\
P_{\rho \underline{d}}(d)=\sum_{x} P_{\underline{d} \mid \underline{x}}(d \mid x) P_{\underline{x}}(x)  \tag{39.9}\\
P\left(\tilde{d}^{\sigma}\right)= \begin{cases}\delta\left(\tilde{d}^{\sigma},\left(\tilde{d}^{\sigma}\right)^{\prime}\right) & \text { for } G_{d o} \\
P_{\rho \underline{d}}\left(\tilde{d}^{\sigma}\right) & \text { for } G_{d o+}\end{cases}  \tag{39.10}\\
P\left(y^{\sigma} \mid x^{\sigma}, \tilde{d}^{\sigma}\right)=P_{\underline{y} \mid \underline{x}, \underline{d}}\left(y^{\sigma} \mid x^{\sigma}, \tilde{d}^{\sigma}\right) \tag{39.11}
\end{gather*}
$$

It is convenient to define the following expected values of $y^{\sigma}$ in terms of the TPMs of bnet $G_{d o+}$ :

$$
\begin{gather*}
\left.\mathcal{Y}_{\mid \tilde{d}, x}=E_{\sigma \mid \tilde{d}, x}\left[\underline{y}^{\sigma}\right] \rightarrow E_{\underline{y} \mid \tilde{d}, x} \underline{y}\right]=\sum_{y} y P(y \mid \tilde{d}, x)  \tag{39.12}\\
\mathcal{Y}_{\mid \tilde{d}}=E_{\sigma \mid \tilde{d}}\left[\underline{y}^{\sigma}\right] \rightarrow E_{y|\tilde{d}| \underline{y}]}=\sum_{x} \mathcal{Y}_{\mid \tilde{d}, x} P(x)  \tag{39.13}\\
\mathcal{Y}_{\mid x}=E_{\sigma \mid x}\left[\underline{y}^{\sigma}\right] \rightarrow E_{y \mid x}[\underline{y}]=\sum_{\tilde{d}} \mathcal{Y}_{\mid \tilde{d}, x} P(\tilde{d})  \tag{39.14}\\
\mathcal{Y}=E_{\sigma}\left[\underline{y}^{\sigma}\right] \rightarrow E_{y}[\underline{y}]=\sum_{\tilde{d}, x} \mathcal{Y}_{\mid \tilde{d}, x} P_{\underline{d} \mid \underline{x}}(\tilde{d} \mid x) P(x) \tag{39.15}
\end{gather*}
$$

## $39.3 G_{i m+}$ bnet

Fig 39.4 shows how bnet $G_{i m}$ is obtained by applying an imagine operator to bnet $G$, and how bnet $G_{i m+}$ is obtained by adding a prior probability distribution to one of the nodes of $G_{i m} . \underline{d} \in\{0,1\}$ represents the dose that a patient is told to take by a doctor, and $\underline{\tilde{d}} \in\{0,1\}$ represents the dose he actually takes. If $\underline{d}=\underline{\tilde{d}}$, the patient is compliant, and if $\underline{d} \neq \underline{d}$, he is non-compliant.

The TPMs, printed in blue, for the nodes of bnets $G_{i m}$ and $G_{i m+}$, are as follows. Note that the TPMs for bnets $G_{i m}$ and $G_{i m+}$ are defined in terms of the

G

$G_{i m}=\kappa_{\underline{d}^{\sigma} \rightarrow \underline{y}^{\sigma}}\left(\tilde{d}^{\sigma}\right) G$

$G_{i m+}$

Figure 39.4: Bnet $G_{i m}=\kappa_{\underline{d}^{\sigma} \rightarrow \underline{y}^{\sigma}}\left(\tilde{d}^{\sigma}\right) G$ is obtained by applying the imagine operator to arrow $\underline{d}^{\sigma} \rightarrow{\underset{\tilde{d}}{ }}^{\sigma}$ of bnet $\underset{\sim}{\sigma}$. Bnet $G_{i m+}$ is obtained by adding a prior probability distribution $P\left(\widetilde{\tilde{d}^{\sigma}}\right)$ to node $\underline{\tilde{d}}^{\sigma}$ of bnet $G_{i m}$.

TPMs of bnet $G$. Note that the prior $P(\tilde{d})$ is not arbitrary; it's calculated from the TPMs of bnet $G$.

$$
\begin{gather*}
P\left(x^{\sigma}\right)=P_{\underline{x}}\left(x^{\sigma}\right)  \tag{39.16}\\
P\left(d^{\sigma} \mid x^{\sigma}\right)=P_{\underline{d} \mid \underline{x}}\left(d^{\sigma} \mid x^{\sigma}\right)  \tag{39.17}\\
\pi_{\tilde{d}}=P(\tilde{d})=\sum_{x} P_{\underline{d} \mid \underline{x}}(\tilde{d} \mid x) P_{\underline{x}}(x)  \tag{39.18}\\
P\left(\tilde{d}^{\sigma}\right)= \begin{cases}\delta\left(\tilde{d}^{\sigma},\left(\tilde{d}^{\sigma}\right)^{\prime}\right) & \text { for } G_{i m} \\
\pi_{\tilde{d}^{\sigma}} & \text { for } G_{i m+}\end{cases}  \tag{39.19}\\
P\left(y^{\sigma} \mid x^{\sigma}, \tilde{d}^{\sigma}\right)=P_{\underline{y} \mid x, \underline{d}}\left(y^{\sigma} \mid x^{\sigma}, \tilde{d}^{\sigma}\right) \tag{39.20}
\end{gather*}
$$

## $39.4 G_{i m+}$ bnet with nodes $y^{\sigma}(0), y^{\sigma}(1)$ added to it.

Consider Fig. 39.5, which was obtained by adding two new nodes $\underline{y}^{\sigma}(0)$ and $\underline{y}^{\sigma}(1)$ to bnets $G_{i m}$ and $G_{i m+}$ in Fig 39.4. The TPMs, printed in blue, for bnets $G_{i m}$ and $G_{i m+}$, are as follows. Note that we define them in terms of the TPMs for bnet $G$.

$$
\begin{gather*}
P\left(x^{\sigma}\right)=P_{\underline{x}}\left(x^{\sigma}\right)  \tag{39.21}\\
P\left(d^{\sigma} \mid x^{\sigma}\right)=P_{\underline{d} \mid \underline{x}}\left(d^{\sigma} \mid x^{\sigma}\right) \tag{39.22}
\end{gather*}
$$

$G$

$G_{i m}=\kappa_{\underline{d}^{\sigma} \rightarrow \underline{y}^{\sigma}}\left(\tilde{d}^{\sigma}\right) G$

$G_{i m+}$

Figure 39.5: Fig 39.4 with two new nodes $\underline{y}^{\sigma}(0)$ and $\underline{y}^{\sigma}(1)$ added to bnets $G_{i m}$ and $G_{i m+}$.

$$
\begin{gather*}
\pi_{\tilde{d}}=P(\tilde{d})=\sum_{x} P_{\underline{d} \underline{\mid x}}(\tilde{d} \mid x) P_{\underline{x}}(x)  \tag{39.23}\\
P\left(\tilde{d}^{\sigma}\right)= \begin{cases}\delta\left(\tilde{d}^{\sigma},\left(\tilde{d}^{\sigma}\right)^{\prime}\right) & \text { for } G_{i m} \\
\pi_{\tilde{d}^{\sigma}} & \text { for } G_{i m+}\end{cases}  \tag{39.24}\\
P\left(y^{\sigma}(0) \mid \tilde{d}^{\sigma}, x^{\sigma}\right)=P_{\underline{y}(0) \mid \tilde{d}, \underline{x}}\left(y^{\sigma}(0) \mid \tilde{d}^{\sigma}, x^{\sigma}\right)  \tag{39.25}\\
P\left(y^{\sigma}(1) \mid \tilde{d}^{\sigma}, x^{\sigma}\right)=P_{\underline{y}(1) \mid \underline{d}, \underline{x}}\left(y^{\sigma}(1) \mid \tilde{d}^{\sigma}, x^{\sigma}\right)  \tag{39.26}\\
P\left(y^{\sigma} \mid y^{\sigma}(0), y^{\sigma}(1), \tilde{d}^{\sigma}\right)==\mathbb{1}\left(y^{\sigma}=\tilde{d}^{\sigma} y^{\sigma}(1)+\left(1-\tilde{d}^{\sigma}\right) y^{\sigma}(0)\right)  \tag{39.27}\\ \tag{39.28}
\end{gather*}
$$

For this bnet, the following is true:

$$
\begin{align*}
P\left(y^{\sigma} \mid \tilde{d}^{\sigma}, x^{\sigma}\right) & =\sum_{y^{\sigma}(0)} \sum_{y^{\sigma}(1)} \mathbb{1}\left(y^{\sigma}=y^{\sigma}\left(\tilde{d}^{\sigma}\right)\right) P\left(y^{\sigma}(0) \mid \tilde{d}^{\sigma}, x^{\sigma}\right) P\left(y^{\sigma}(1) \mid \tilde{d}^{\sigma}, x^{\sigma}\right)  \tag{39.29}\\
& =\left\{\begin{array}{ll}
P_{\underline{y}(0) \mid \tilde{d}, \underline{x}}\left(y^{\sigma} \mid \tilde{d}^{\sigma}, x^{\sigma}\right) & \text { if } \tilde{d}^{\sigma}=0 \\
P_{\underline{y}(1) \mid \tilde{d}, \underline{x}}\left(y^{\sigma} \mid \tilde{d}^{\sigma}, x^{\sigma}\right) & \text { if } \tilde{d}^{\sigma}=1
\end{array} .\right. \tag{39.30}
\end{align*}
$$

Note that $P_{\underline{y}(0) \mid \tilde{d}, x}$ and $P_{\underline{y}(1) \mid \tilde{d}, x}$ are possibly different functions and that $P_{\underline{y} \mid \tilde{d}, x}$ is defined in terms of both of them. Eq. 39.30 implies that for this bnet,

$$
\begin{align*}
\underline{y}^{\sigma} & =\mathbb{1}\left(\tilde{d}^{s}=1\right) \underline{y}^{\sigma}(1)+\mathbb{1}\left(\tilde{d}^{s}=0\right) \underline{y}^{\sigma}(0)  \tag{39.31}\\
& =\tilde{d}^{\sigma} \underline{y}^{\sigma}(1)+\left(1-\tilde{d}^{s}\right) \underline{y}^{\sigma}(0)  \tag{39.32}\\
& =\underline{y}^{\sigma}\left(\tilde{d}^{\sigma}\right) \tag{39.33}
\end{align*}
$$

These are all different ways of saying the same thing.
It is convenient to define the following expected values of $\underline{y}^{\sigma}$ in terms of the TPMs of bnet $G_{i m+}$ :

$$
\begin{array}{r}
\mathcal{Y}_{d \mid \tilde{d}, x}=E_{\sigma \mid \tilde{d}, x}\left[\underline{y}^{\sigma}(d)\right] \rightarrow E_{\underline{y} \mid \tilde{d}, x}[\underline{y}(d)]=\sum_{y} P(y(\tilde{d}) \mid \tilde{d}, x) y(\tilde{d}) \\
\left.\mathcal{Y}_{d \mid \tilde{d}}=E_{\sigma \mid \tilde{d}} \underline{y}^{\sigma}(d)\right] \rightarrow E_{\underline{y} \mid \tilde{d}}[\underline{y}(d)]=\sum_{x} \mathcal{Y}_{d \mid \tilde{d}, x} P(x) \\
\mathcal{Y}_{d \mid x}=E_{\sigma \mid x}\left[\underline{y}^{\sigma}(d)\right] \rightarrow E_{\underline{y} \mid x}[\underline{y}(d)]=\sum_{\tilde{d}} \mathcal{Y}_{d \mid \tilde{d}, x} P(\tilde{d}) \\
\mathcal{Y}_{d}=E_{\sigma}\left[\underline{y}^{\sigma}(d)\right] \rightarrow E_{\underline{y}}[\underline{y}(d)]=\sum_{\tilde{d}, x} \mathcal{Y}_{d \mid \tilde{d}, x} P_{\underline{d} \mid \underline{x}}(\tilde{d} \mid x) P(x) \tag{39.37}
\end{array}
$$

$\mathcal{Y}_{0 \mid 0}, \mathcal{Y}_{1 \mid 1}$ are said to be factual (indicating compliant patients) whereas $\mathcal{Y}_{0 \mid 1}, \mathcal{Y}_{1 \mid 0}$ are said to be counterfactual (indicating non-compliant patients).

### 39.5 Conditional Independence Assumption

The Conditional Independence Assumption (CIA) is said to hold if

$$
\begin{equation*}
\left(\underline{y}^{\sigma}(0), \underline{y}^{\sigma}(1), \underline{y}^{\sigma}, \underline{\tilde{d}}^{\sigma}\right) \perp_{P} \underline{d}^{\sigma} \mid \underline{x}^{\sigma} . \tag{39.38}
\end{equation*}
$$

This is satisfied by $G_{i m}$. To prove this, check that

$$
\begin{equation*}
\left(\underline{y}^{\sigma}(0), \underline{y}(1), \underline{y}^{\sigma}, \underline{\tilde{d}}^{\sigma}\right) \perp_{G_{i m}} \underline{d}^{\sigma} \mid \underline{x}^{\sigma} \tag{39.39}
\end{equation*}
$$

and then invoke the d-separation theorem (see Chapter 14).
Note that the following are also true

$$
\begin{gather*}
\left(\underline{y}^{\sigma}(0), \underline{y}(1)\right) \perp_{G_{i m}} \underline{\tilde{d}}^{\sigma} \mid \underline{x}^{\sigma}  \tag{39.40}\\
\left(\underline{y}^{\sigma}(0), \underline{y}(1)\right) \perp_{G_{i m}} \underline{\tilde{d}}^{\sigma} \tag{39.41}
\end{gather*}
$$

by the d-separation theorem, because $\underline{y}^{\sigma}$ acts as a collider on all paths from $\underline{y}^{\sigma}(d)$ to $\underline{\tilde{d}}^{\sigma}$ for $d \in\{0,1\}$. However,

$$
\begin{equation*}
\underline{y}^{\sigma} \perp_{G_{i m}} \underline{\tilde{d}}^{\sigma} \mid \underline{x}^{\sigma} \quad \text { is FALSE. } \tag{39.42}
\end{equation*}
$$

Note that even though CIA means $\underline{\tilde{d}}^{\sigma} \perp_{G_{i m}} \underline{d}^{\sigma} \mid x^{\sigma}$, this does not mean that $\mathcal{Y}_{d \mid \tilde{d}, x}=\mathcal{Y}_{d \mid x x}$. The reason is that $\mathcal{Y}_{d \mid \tilde{d}, x}=E_{\mid \tilde{d} \sigma}=\tilde{d}, x\left[\underline{y}^{\sigma}(d)\right]$ so $\mathcal{Y}_{d \mid \tilde{d}, x}=\mathcal{Y}_{d \mid x}$ if $\underline{y}^{\sigma}(d) \perp_{G_{i m}}$ $\underline{\tilde{d}}^{\sigma} \mid \underline{x}^{\sigma}$, which is false. It is possible for $\mathcal{Y}_{d \mid \tilde{d}, x}=\mathcal{Y}_{d \mid x}$ to be true. We discuss that situation in Section 39.9,

## $39.6 \mathcal{Y}_{\mid \tilde{d}, x}$ and $G_{d o}$

Note that $\mathcal{Y}_{d \mid x}$ and $\mathcal{Y}_{\mid \tilde{d}, x}$ are not the same thing.

$$
\begin{equation*}
\mathcal{Y}_{d \mid x}=E_{\mid x}[\underline{y}(d)] \tag{39.43}
\end{equation*}
$$

whereas

$$
\begin{equation*}
\mathcal{Y}_{\mid \tilde{d}, x}=E_{\mid \tilde{d}, x}[\underline{y}] . \tag{39.44}
\end{equation*}
$$

## Claim 26

$$
\begin{equation*}
\mathcal{Y}_{\mid \tilde{d}, x}=\mathcal{Y}_{\tilde{d} \mid \tilde{d}, x} \tag{39.45}
\end{equation*}
$$

proof:

$$
\begin{align*}
\mathcal{Y}_{\tilde{d} \mid \tilde{d}, x} & =\tilde{d} \mathcal{Y}_{1 \mid \tilde{d}, x}+(1-\tilde{d}) \mathcal{Y}_{0 \mid \tilde{d}, x}  \tag{39.46}\\
& \left.=\tilde{d} E_{\mid \tilde{d}, x}[\underline{y}(1)]+(1-\tilde{d}) E_{\mid \tilde{d}, x} \underline{y}(0)\right]  \tag{39.47}\\
& \left.=E_{\mid \tilde{d} x}[\underline{d} \underline{y}(1)]+(1-\tilde{d}) \underline{y}(0)\right]  \tag{39.48}\\
& =E_{\mid \tilde{d}, x}[\underline{y}]  \tag{39.49}\\
& =\mathcal{Y}_{\mid \tilde{d}, x} \tag{39.50}
\end{align*}
$$

## QED

$\mathcal{Y}_{\mid \tilde{d}, x}$ is connected to the do operator as follows.

$$
\begin{equation*}
\mathcal{Y}_{\mid \tilde{d}, x}=\sum_{y} y P(\underline{y}=y \mid \rho \underline{d}=\tilde{d}, \underline{x}=x), \tag{39.51}
\end{equation*}
$$

where

$$
\begin{equation*}
P(\underline{y}=y \mid \rho \underline{d}=\tilde{d}, \underline{x}=x)=P(y \mid \tilde{d}, x) . \tag{39.52}
\end{equation*}
$$

In particular, when $\underline{y}$ is binary (i.e., $\underline{y} \in\{0,1\}$ ), Eq. 39.51 becomes

$$
\begin{equation*}
\mathcal{Y}_{\mid \tilde{d}, x}=P(\underline{y}=1 \mid \rho \underline{d}=\tilde{d}, \underline{x}=x) . \tag{39.53}
\end{equation*}
$$

### 39.7 Translation Dictionary

| In standard PO notation | In our notation (for $G_{i m}$ or $G_{i m+}$ ) |
| :--- | :--- |

Table 39.2: Dictionary for translating from standard PO notation of Ref. 3 to our notation.

Table 39.2 gives a dictionary for translating from the standard PO notation of Ref.[3] to our notation. $d, \tilde{d} \in\{0,1\}$. I find the standard PO notation confusing because it often uses $D_{i}$ to represent two different nodes, $\underline{d}^{\sigma}$ and $\underline{\tilde{d}}^{\sigma}$ in $G_{i m+}$. This confusion becomes particularly distressing when we are told in PO notation that

$$
\begin{equation*}
Y_{i}(d)=d Y_{i}(1)+(1-d) Y_{i}(0) \tag{39.54}
\end{equation*}
$$

and

$$
\begin{equation*}
E\left[Y_{i}(d) \mid D_{i}=\tilde{d}, X_{i}=x\right]=\mathcal{Y}_{d \mid \tilde{d}, x} \tag{39.55}
\end{equation*}
$$

In our notation, this is saying that

$$
\begin{equation*}
\underline{y}^{\sigma}(d)=d \underline{y}^{\sigma}(1)+(1-d) \underline{y}^{\sigma}(0), \tag{39.56}
\end{equation*}
$$

and

$$
\begin{equation*}
E_{\sigma \mid \underline{d}^{\sigma}=\tilde{d}, \underline{x}^{\sigma}=x}\left[\underline{y}^{\sigma}(d)\right]=\mathcal{Y}_{d \mid \tilde{d}, x} . \tag{39.57}
\end{equation*}
$$

## $39.8 \mathcal{Y}_{d \mid \tilde{d}}$ differences (aka treatment effects)

It is convenient to define the following treatment effects. See Fig.39.6. Note that we use the word "effect" to refer to a difference of two $\mathcal{Y}_{d \mid \underline{d}}$.

Figure 39.6: Different treatment effects. An effect is a difference of two $\mathcal{Y}_{d \mid \tilde{d}}$.

- average controlled causal effect (ACE), used when doing an RCT.

$$
\begin{equation*}
A C E=\mathcal{Y}_{\mid 1}-\mathcal{Y}_{\mid 0}=\mathcal{Y}_{1 \mid 1}-\mathcal{Y}_{0 \mid 0}=S D O \tag{39.58}
\end{equation*}
$$

- average treatment effect ${ }^{2}$ (ATE).

$$
\begin{equation*}
A T E=\mathcal{Y}_{1}-\mathcal{Y}_{0}=\delta \tag{39.59}
\end{equation*}
$$

- average treatment effect of the treated (ATT)

$$
\begin{equation*}
A T T=\mathcal{Y}_{1 \mid 1}-\mathcal{Y}_{0 \mid 1} \tag{39.60}
\end{equation*}
$$

- average treatment effect of the untreated (ATU)

$$
\begin{equation*}
A T U=\mathcal{Y}_{1 \mid 0}-\mathcal{Y}_{0 \mid 0} \tag{39.61}
\end{equation*}
$$

- selection bias (SB)

$$
\begin{equation*}
S B=\mathcal{Y}_{0 \mid 1}-\mathcal{Y}_{0 \mid 0} \tag{39.62}
\end{equation*}
$$

- simple difference in outcomes (SDO)

$$
\begin{equation*}
S D O=\mathcal{Y}_{1 \mid 1}-\mathcal{Y}_{0 \mid 0} \tag{39.63}
\end{equation*}
$$

Note that some of these effects are linearly related

$$
\begin{align*}
& \underbrace{\mathcal{Y}_{1}-\mathcal{Y}_{0}}_{A T E}=\underbrace{\left(\mathcal{Y}_{1 \mid 1}-\mathcal{Y}_{0 \mid 1}\right)}_{A T T} \pi_{1}+\underbrace{\left(\mathcal{Y}_{1 \mid 0}-\mathcal{Y}_{0 \mid 0}\right)}_{A T U} \pi_{0}  \tag{39.64}\\
& \underbrace{\mathcal{Y}_{1 \mid 1}-\mathcal{Y}_{0 \mid 0}}_{S D O}=\underbrace{\left(\mathcal{Y}_{1 \mid 1}-\mathcal{Y}_{0 \mid 1}\right)}_{A T T}+\underbrace{\mathcal{Y}_{0 \mid 1}-\mathcal{Y}_{0 \mid 0}}_{S B} \tag{39.65}
\end{align*}
$$

[^21]\[

$$
\begin{align*}
\underbrace{\mathcal{Y}_{1 \mid 1}-\mathcal{Y}_{0 \mid 0}}_{S D O}= & \underbrace{\left(\mathcal{Y}_{1 \mid 1}-\mathcal{Y}_{0 \mid 1}\right) \pi_{1}+\left(\mathcal{Y}_{1 \mid 0}-\mathcal{Y}_{0 \mid 0}\right) \pi_{0}}_{A T E}  \tag{39.66}\\
& +\underbrace{\mathcal{Y}_{0 \mid 1}-\mathcal{Y}_{0 \mid 0}}_{S B}  \tag{39.67}\\
& +\underbrace{\left(\mathcal{Y}_{1 \mid 1}-\mathcal{Y}_{0 \mid 1}\right)}_{A T T} \pi_{0}  \tag{39.68}\\
& -\underbrace{\left(\mathcal{Y}_{1 \mid 0}-\mathcal{Y}_{0 \mid 0}\right)}_{A T U} \pi_{0} \tag{39.69}
\end{align*}
$$
\]

Let $\mathcal{E} \in\{A C E, A T E, A T T, A T U, S D O, S B\}$. $\mathcal{E}$ can be defined for a fixed stratum $x$ by replacing $\mathcal{Y}_{d \mid \tilde{d}}$ with $\mathcal{Y}_{d \mid \tilde{d} x}$. We will denote such an extension by $\mathcal{E}_{\mid x}$, or, sometimes, simply by $\mathcal{E} . \mathrm{ATE}_{\mid x}$ is sometimes called the Conditional Average Treatment Effect (CATE). We will use the term ATE to refer to CATE too.$^{3}$

### 39.9 Zero ACE, $\mathcal{Y}_{1 \mid 0}=\mathcal{Y}_{1}$

Figure 39.7: Figure 39.6 with added information about probability distributions used to obtain each expected value $\mathcal{Y}_{d \mid \tilde{d}}$.
$S D O=0$ is the hypothesis tested by a Randomized Control Trial (RCT). But some people test for $A T E=0$ instead.

1. Is it possible for $S D O=0$ but $A T E \neq 0$ or vice versa, and what is going on when this is true?
2. What is going on when two treatment effects are equal; for instance, when $A T T=A T U ?$

[^22]3. When is $\mathcal{Y}_{1 \mid 0}=\mathcal{Y}_{1}$, and what is going on when this is true?

Fig 39.7 gives some intuition about what is going on when any of these things happen.
Recall that each expected value $\mathcal{Y}$ has a probability distribution $P$.

$$
\begin{equation*}
\mathcal{Y}_{d \mid \tilde{d}, x}=\sum_{y} y P_{\underline{y}(d) \mid \tilde{d}, \underline{x}}(y \mid \tilde{d}, x) \tag{39.70}
\end{equation*}
$$

for $d, \tilde{d} \in\{0,1\}$. Fig 39.7 reminds us of which $P$ is used to generate each $\mathcal{Y}$. From this figure, we see that

1. A sufficient condition for $S D O=0$ is that $P_{\underline{y}(1) \mid \underline{d}=1, \underline{x}}=P_{\underline{y}(0) \mid \underline{\tilde{d}}=0, \underline{x}}$. Since $A T E=$ 0 iff $A T T=A T U=0$, a sufficient condition for $A T E=0$ is that $P_{\underline{y}(1) \mid \underline{d}=0, \underline{x}}=$ $P_{\underline{y}(0) \mid \underline{\tilde{d}}=0, \underline{x}}$ and $P_{\underline{y}(1) \mid \underline{\tilde{d}}=1, \underline{x}}=P_{\underline{y}(0) \mid \underline{\tilde{d}}=1, \underline{x}}$.
2. A sufficient condition for $A T T=A T U$ is that $P_{\underline{y}(1) \mid \underline{\tilde{d}}=0, \underline{x}}-P_{\underline{y}(0) \mid \underline{\tilde{d}}=0, \underline{x}}$ equals $P_{\underline{y}(1) \mid \underline{\tilde{d}}=1, \underline{x}}-P_{\underline{y}(0) \mid \underline{\tilde{d}}=1, \underline{x}}$.
3. If we assume that all $y^{\sigma}>0, \mathcal{Y}_{1 \mid 0}=\mathcal{Y}_{1}$ iff $P_{\underline{\underline{y}}(1) \mid \underline{\tilde{d}}=0, \underline{x}}=P_{\underline{y}(1) \mid \underline{x}}$.
$S D O=0$ depends on two corners of the square whereas $\mathcal{Y}_{1 \mid 0}=\mathcal{Y}_{1}$ depends on just one corner.

### 39.10 (SDO, ATE) space

If we substitute $y^{\sigma} \rightarrow y^{\sigma}\left(\tilde{d}^{\sigma}\right)$ and $y^{s(\sigma)} \rightarrow y^{\sigma}\left(!\tilde{d}^{\sigma}\right)$, where $!0=1$ and $!1=0$, into the estimator Eq. (39.81) for $A T E$ and the estimator Eq. (39.87) for $S D O$, we get

$$
\begin{align*}
\widehat{A T E} & =\frac{1}{N_{x}} \sum_{\sigma \in A_{x}}\left(2 \tilde{d}^{\sigma}-1\right)\left[y^{\sigma}\left(\tilde{d}^{\sigma}\right)-y^{\sigma}\left(!\tilde{d}^{\sigma}\right)\right]  \tag{39.71}\\
& =\frac{1}{N_{x}} \sum_{\sigma \in A_{x}}\left[y^{\sigma}(1)-y^{\sigma}(0)\right] \tag{39.72}
\end{align*}
$$

and

$$
\begin{align*}
\widehat{S D O} & =\frac{1}{N_{1, x}} \sum_{\sigma \in A_{x}} \tilde{d}^{\sigma} y^{\sigma}\left(\tilde{d}^{\sigma}\right)-\frac{1}{N_{0, x}} \sum_{\sigma \in A_{x}}\left(1-\tilde{d}^{\sigma}\right) y^{\sigma}\left(\tilde{d}^{\sigma}\right)  \tag{39.73}\\
& =\frac{1}{N_{1, x}} \sum_{\sigma \in A_{1, x}} y^{\sigma}(1)-\frac{1}{N_{0, x}} \sum_{\sigma \in A_{0, x}} y^{\sigma}(0) \tag{39.74}
\end{align*}
$$

$S D O=0$ is the hypothesis tested by a Randomized Clinical Trial (RTC).
Suppose that the treatment outcome $y^{\sigma}$ has only two possible values, 0 and 1. Then, $-1 \leq A T E \leq 1$ and $-1 \leq S D O \leq 1$. But does $A T E=0$ imply $S D O=0$ or vice versa? Next, we answer that question and more by finding the region of accessibility in the $(S D O, A T E)$ plane, assuming $y^{\sigma} \in\{0,1\}$.

| $\sigma$ | $\tilde{d}^{\sigma}$ | $y^{\sigma}(0)$ | $y^{\sigma}(1)$ |
| :--- | :--- | :--- | :--- |

(c) $S D O=1(A T E=0)$ point F

Figure 39.9: Examples of PO datasets. Exploring $S D O$ extremes.

Figure 39.10: Green parallelogram is accessible region in ( $S D O, A T E$ ) plane, assuming $y^{\sigma} \in\{0,1\}$. Each of the six points A, B, ..F corresponds to one of the six tables in Figs. 39.8 and 39.9. Point $C$ is ideal. The segment $B E$ is the set of accessible points with zero effect in an RCT.

### 39.11 Matching Strata

For a situation described by the bnet $G_{i m+}$, we can match similar individuals to fill the blank cells of Table 39.1. By "similar", we mean that they have the same or almost the same value of $\underline{x}^{\sigma}$.

IMPORTANT: Matching only makes sense if the individuals are treatment blind (i.e., have no knowledge of whether they are in the treated or control groups.)

### 39.11.1 Exact strata-match

For $\tilde{d} \in\{0,1\}$ and all strata $x$, define the sets of individuals $A_{\tilde{d}, x}=\left\{\sigma: \tilde{d}^{\sigma}=\tilde{d}, x^{\sigma}=\right.$ $x\}, A_{x}=A_{0, x} \cup A_{1, x}$ and $A=\cup_{x} A_{x}$. Let $N_{d, x}=\left|A_{d, x}\right|, N_{x}=\left|A_{x}\right|$ and $N=|A|$.

In an exact strata-match, we match each individual with $\tilde{d}^{\sigma}=1, x^{\sigma}=x$ with exactly one individual with $\tilde{d}^{\sigma}=0, x^{\sigma}=x$ and vice versa. Define a map $s: A \rightarrow A$ such that, for each $x, s\left(A_{0, x}\right) \subset A_{1, x}$ and $s\left(A_{1, x}\right) \subset A_{0, x}$. This assumes $A_{0, x}$ and $A_{1, x}$ are non-empty for all $x$. The purpose of map $s()$ is to fill in the missing data in the PO dataset. See Fig 39.3 for a pictorial representation of this.

|  | $y^{\sigma}(0)$ | $y^{\sigma}(1)$ |
| :--- | :--- | :--- |
| $\tilde{d}^{\sigma}=0$ | $y^{\sigma}$ | $y^{s(\sigma)}$ |
| $\tilde{d}^{\sigma}=1$ | $y^{s(\sigma)}$ | $y^{\sigma}$ |

Table 39.3: Illustration of the purpose of the map $s()$. Note that $y^{\sigma}=y^{\sigma}\left(\tilde{d}^{\sigma}\right)$ and $y^{s(\sigma)}=y^{\sigma}\left(!\tilde{d}^{\sigma}\right)$, where $!0=1$ and $!1=0$.

Note that

$$
\begin{equation*}
E_{\mid x}\left[\underline{\tilde{d}}^{\sigma} \underline{y}^{\sigma}\right] \neq E_{\mid x}\left[\underline{\tilde{d}}^{\sigma}\right] \quad E_{\mid x}\left[\underline{y}^{\sigma}\right] \tag{39.75}
\end{equation*}
$$

but

$$
\begin{equation*}
E_{\mid x}\left[\underline{d}^{\sigma} \underline{y}^{\sigma}\right]=E_{\mid x}\left[\underline{d}^{\sigma}\right] \quad E_{\mid x}\left[\underline{y}^{\sigma}\right] \tag{39.76}
\end{equation*}
$$

because, by d-separation, at fixed $x, \underline{y}^{\sigma}$ and $\underline{\tilde{d}}^{\sigma}$ are not independent but $\underline{y}^{\sigma}$ and $\underline{d}^{\sigma}$ are. Table 39.4 evaluates various expected values of the type $E_{\mid x}\left[\underline{d}^{\sigma} \underline{y}^{\sigma}\right]$.

Recall that

$$
\begin{gather*}
A C E=S D O  \tag{39.77a}\\
A T E=A T T \quad P_{\underline{d} \mid \underline{x}}(1 \mid x)+A T U \quad P_{\underline{d} \mid \underline{x}}(0 \mid x)  \tag{39.77b}\\
A T T=\mathcal{Y}_{1 \mid 1, x}-\mathcal{Y}_{0 \mid 1, x}  \tag{39.77c}\\
A T U=\mathcal{Y}_{1 \mid 0, x}-\mathcal{Y}_{0 \mid 0, x} \tag{39.77d}
\end{gather*}
$$

|  | $y^{\sigma}(0)$ | $y^{\sigma}(1)$ |
| :--- | :--- | :--- |
| $\tilde{d}^{\sigma}=0$ | $E_{\mid x}\left[\left(1-\underline{\tilde{d}}^{\sigma}\right) \underline{y}^{\sigma}\right]=E\left[1-\tilde{\tilde{d}}^{\sigma}\right] \mathcal{Y}_{0 \mid 0, x}$ | $E_{\mid x}\left[\left(1-\underline{\tilde{d}}^{\sigma}\right) \underline{y}^{s(\sigma)}\right]=E\left[1-\underline{\tilde{d}}^{\sigma}\right] \mathcal{Y}_{1 \mid 0, x}$ |
|  | $E_{\mid x}\left[\frac{1}{N_{0, x}} \sum_{\sigma \in A_{x}}\left(1-\underline{\tilde{d}}^{\sigma}\right) \underline{y}^{\sigma}\right]=\mathcal{Y}_{0 \mid 0, x}$ | $E_{\mid x}\left[\frac{1}{N_{0, x}} \sum_{\sigma \in A_{x}}\left(1-\tilde{\tilde{d}}^{\sigma}\right) \underline{y}^{s(\sigma)}\right]=\mathcal{Y}_{1 \mid 0, x}$ |
| $\tilde{d}^{\sigma}=1$ | $E_{\mid x}\left[\tilde{\tilde{d}}^{\sigma} \underline{y}^{\sigma}\right]=E\left[\underline{\tilde{d}}^{s(\sigma)}\right] \mathcal{Y}_{0 \mid 1, x}$ | $E_{\mid x}\left[\tilde{\tilde{d}}^{\sigma} \underline{y}^{\sigma}\right]=E\left[\underline{\tilde{d}}^{\sigma}\right] \mathcal{Y}_{1 \mid 1, x}$ |
| $E_{\mid x}\left[\frac{1}{N_{1, x}} \sum_{\sigma \in A_{x}} \underline{\tilde{d}}^{\sigma} \underline{y}^{s(\sigma)}\right]=\mathcal{Y}_{0 \mid 1, x}$ | $E_{\mid x}\left[\frac{1}{N_{1, x}} \sum_{\sigma \in A_{x}} \underline{\tilde{d}}^{\sigma} \underline{y}^{\sigma}\right]=\mathcal{Y}_{1 \mid 1, x}$ |  |

Table 39.4: Expected Values of the type $E_{\mid x}\left[\underline{\tilde{d}}^{\sigma} \underline{y}^{\sigma}\right]$.

$$
\begin{gather*}
S B=\mathcal{Y}_{0 \mid 1, x}-\mathcal{Y}_{0 \mid 0, x}  \tag{39.77e}\\
S D O=\mathcal{Y}_{1 \mid 1, x}-\mathcal{Y}_{0 \mid 0, x} \tag{39.77f}
\end{gather*}
$$

Eqs. 39.77) can be estimated from the data via the following estimators.

$$
\begin{align*}
& \widehat{A C E}=\widehat{S D O}  \tag{39.78}\\
& \widehat{A T E}= \frac{1}{N_{x}}\left[\widehat{A T T} N_{1, x}+\widehat{A T U} N_{0, x}\right]  \tag{39.79}\\
&= \frac{1}{N_{x}}\left[\sum_{\sigma \in A_{x}} \tilde{d}^{\sigma}\left[y^{\sigma}-y^{s(\sigma)}\right]+\sum_{\sigma \in A_{x}}\left(1-\tilde{d}^{\sigma}\right)\left[y^{s(\sigma)}-y^{\sigma}\right]\right]  \tag{39.80}\\
&= \frac{1}{N_{x}} \sum_{\sigma \in A_{x}}\left(2 \tilde{d}^{\sigma}-1\right)\left[y^{\sigma}-y^{s(\sigma)}\right]  \tag{39.81}\\
& \widehat{A T T}= \overbrace{\frac{1}{N_{1, x}} \sum_{\sigma \in A_{x}} \tilde{d}^{\sigma} y^{\sigma}}^{\mathcal{Y}_{1 \mid 1, x}}-\overbrace{\frac{1}{N_{1, x}} \sum_{\sigma \in A_{x}}^{\mathcal{Y}_{0 \mid 1, x}} \tilde{d}^{\sigma} y^{s(\sigma)}}^{N_{1, x}} \sum_{\sigma \in A_{x}} \tilde{d}^{\sigma}\left[y^{\sigma}-y^{s(\sigma)}\right]  \tag{39.82}\\
& \widehat{A T U}= \overbrace{\frac{1}{N_{0, x}} \sum_{\sigma \in A_{x}}\left(1-\tilde{d}^{\sigma}\right) y^{s(\sigma)}} \begin{aligned}
\mathcal{Y}_{\frac{1}{1}}^{N_{0, x}} \sum_{\sigma \in A_{x}}\left(1-\tilde{d}^{\sigma}\right) y^{\sigma}
\end{aligned}  \tag{39.83}\\
&= \frac{1}{N_{0, x}} \sum_{\sigma \in A_{x}}\left(1-\tilde{d}^{\sigma}\right)\left[y^{s(\sigma)}\right. \tag{39.84}
\end{align*}
$$

$$
\begin{align*}
& \widehat{S B}=\overbrace{\frac{1}{N_{1, x}} \sum_{\sigma \in A_{x}} \tilde{d}^{\sigma} y^{s(\sigma)}}^{\mathcal{Y}_{0 \mid 1, x}}-\overbrace{\frac{1}{N_{0, x}} \sum_{\sigma \in A_{x}}\left(1-\tilde{d}^{\sigma}\right) y^{\sigma}}^{\mathcal{Y}_{0 \mid 0, x}}  \tag{39.86}\\
& \widehat{S D O}=\overbrace{\frac{1}{N_{1, x}} \sum_{\sigma \in A_{x}} \tilde{d}^{\sigma} y^{\sigma}}^{\mathcal{Y}_{1 \mid 1, x}}-\overbrace{\frac{1}{N_{0, x}} \sum_{\sigma \in A_{x}}\left(1-\tilde{d}^{\sigma}\right) y^{\sigma}}^{\mathcal{Y}_{0 \mid 0, x}} \tag{39.87}
\end{align*}
$$

We've said before that strata matching makes no sense unless every individual is treatment blind. This means that if the individuals are not treatment blind, the above estimators for $A T E, A T T, A T U, S B$ are invalid because they depend on $s()$. Only the estimator for $S D O$ is valid because it doesn't depend on $s()$.

Let

$$
\begin{equation*}
g_{d}(x)=P_{\underline{d} \mid \underline{x}}(d \mid x) \tag{39.88}
\end{equation*}
$$

for $d \in\{0,1\}$. Note that $g_{0}(x)+g_{1}(x)=1 . g_{1}(x)$ is called the propensity score. One can do propensity weighting within the above estimators to improve their behavior. This is done by making the following replacements.

$$
\begin{equation*}
N_{1, x} \rightarrow N_{x} g_{1}\left(x^{\sigma}\right), \quad N_{0, x} \rightarrow N_{x} g_{0}\left(x^{\sigma}\right) \tag{39.89}
\end{equation*}
$$

These replacements are equal under $\sum_{\sigma \in A_{x}}$ to the terms they replace.

## Example, calculation of estimators for a treatment

For $\sigma \in\{1,2, \ldots, 10\}$, define

$$
s(\sigma)= \begin{cases}\sigma+5 & \text { if } \sigma \leq 5  \tag{39.90}\\ \sigma-5 & \text { if } \sigma>5\end{cases}
$$

Let $N(\mathcal{S})$ be the number of individuals $\sigma$ that satisfy condition $\mathcal{S}$. For example, $N\left(\underline{\tilde{d}^{\sigma}}=\tilde{d}\right)$ is the number of individuals such that $\underline{\tilde{d}^{\sigma}}=\tilde{d}$.

$$
\begin{gather*}
N_{1}=N\left(\tilde{d}^{\sigma}=1\right)=5  \tag{39.91}\\
N_{0}=N\left(\tilde{d}^{\sigma}=0\right)=5  \tag{39.92}\\
N=N_{0}+N_{1}=10  \tag{39.93}\\
\mathcal{Y}_{1 \mid 1}=\frac{1}{N_{1}} \sum_{\sigma} \tilde{d}^{\sigma} y^{\sigma}=\frac{4}{5} \tag{39.94}
\end{gather*}
$$

| $\sigma$ | $\tilde{d}^{\sigma}$ | $y^{\sigma}$ | $\tilde{d}^{\sigma} y^{\sigma}$ | $\left(1-\tilde{d}^{\sigma}\right) y^{\sigma}$ | $\tilde{d}^{\sigma} y^{s(\sigma)}$ | $\left(1-\tilde{d}^{\sigma}\right) y^{s(\sigma)}$ |
| :---: | :--- | :--- | :--- | :--- | :--- | :--- |
| 1 | 0 | 0 | 0 | 0 | 0 | 0 |
| 2 | 0 | 0 | 0 | 0 | 0 | 1 |
| 3 | 0 | 1 | 0 | 1 | 0 | 1 |
| 4 | 0 | 1 | 0 | 1 | 0 | 1 |
| 5 | 0 | 1 | 0 | 1 | 0 | 1 |
| 6 | 1 | 0 | 0 | 0 | 0 | 0 |
| 7 | 1 | 1 | 1 | 0 | 0 | 0 |
| 8 | 1 | 1 | 1 | 0 | 1 | 0 |
| 9 | 1 | 1 | 1 | 0 | 1 | 0 |
| 10 | 1 | 1 | 1 | 0 | 1 | 0 |

Table 39.5: Estimators of treatment effects are calculated for this example.

| $N(\tilde{d}, y)$ | $y=0$ | $y=1$ |
| :--- | :--- | :--- |
| $\tilde{d}=0$ | 2 | 3 |
| $\tilde{d}=1$ | 1 | 4 |

Table 39.6: $N\left(\underline{\tilde{d}}^{\sigma}=d, \underline{y}^{\sigma}=y\right)$ for the data in Table 39.5.

$$
\begin{gather*}
\mathcal{Y}_{0 \mid 0}=\frac{1}{N_{0}} \sum_{\sigma}\left(1-\tilde{d}^{\sigma}\right) y^{\sigma}=\frac{3}{5}  \tag{39.95}\\
\mathcal{Y}_{0 \mid 1}=\frac{1}{N_{1}} \sum_{\sigma} \tilde{d}^{\sigma} y^{s(\sigma)}=\frac{3}{5}  \tag{39.96}\\
\mathcal{Y}_{1 \mid 0}=\frac{1}{N_{0}} \sum_{\sigma}\left(1-\tilde{d}^{\sigma}\right) y^{s(\sigma)}=\frac{4}{5}  \tag{39.97}\\
A T T=\mathcal{Y}_{1 \mid 1}-\mathcal{Y}_{0 \mid 1}=\frac{1}{5}  \tag{39.98}\\
A T E=A T T=A T U=S D O=\frac{1}{5}, \quad S B=0 \tag{39.99}
\end{gather*}
$$

This example is unusual in that it has a single stratum $x$, and for that stratum, the treated and untreated populations are balanced (of equal size). Also, the map $s()$ is 1-1 onto. If, for instance, $s(\sigma)=6$ for all $\sigma \in A_{0}$ and $s(\sigma)=5$ for $\sigma \in A_{1}$, then $A T E, A T T, A T U, S D O$ would not all be same, and $S B$ would not be zero. In fact,
whenever there is a single balanced stratum and the map $s()$ is $1-1$ onto, Eq 39.99 can be proven to be true using the methods of section 39.9 .

### 39.11.2 Approximate strata-match

It is very often the case that one can't find for a given individual $\sigma$ another individual that has opposite $d^{\sigma}$ but exactly the same value of $x^{\sigma}$. In such cases, one can discard all matchless individuals. But that would entail a loss of precious information. Instead of discarding orphans, a better way is to relax our demands and match individual $\sigma$ with another individual $s(\sigma)$ such that $x^{\sigma}$ and $x^{s(\sigma)}$ are very close in some metric. Alternatively, the matching individual might not be real; it might be a composite of individuals.

More precisely, for some arbitrary parameter $\epsilon>0$, and an individual $\sigma$ with $d^{\sigma}=1$, define the strata-matching set $\mathcal{M}_{\epsilon}(\sigma)$ by ${ }^{4}$

$$
\begin{equation*}
\mathcal{M}_{\epsilon}(\sigma)=\left\{s: d^{\sigma}=1, d^{s}=0, \operatorname{dist}\left(x^{\sigma}, x^{s}\right) \leq \epsilon\right\} \tag{39.100}
\end{equation*}
$$

where

$$
\begin{equation*}
\operatorname{dist}\left(x^{\sigma}, x^{s}\right)=\left[x^{\sigma}\right]^{T}[\Sigma]^{-1} x^{s}, \tag{39.101}
\end{equation*}
$$

where $\Sigma=\left\langle\underline{x}^{\sigma},\left[\underline{x}^{s}\right]^{T}\right\rangle$. This metric $\operatorname{dist}\left(x^{\sigma}, x^{s}\right)$ is called the Mahalanobis distance. We will call the case $\epsilon=0$ an exact strata-match, and the case $\epsilon \neq 0$ an approximate strata-match. To do an approximate strata-match, replace $y^{s(\sigma)}$ by $\langle y\rangle^{\sigma}$ in the estimators given above for an exact strata-match. $\langle y\rangle^{\sigma}$ is defined by

$$
\begin{equation*}
\langle y\rangle^{\sigma}=\frac{1}{\left|\mathcal{M}_{\epsilon}(\sigma)\right|} \sum_{s \in \mathcal{M}_{\epsilon}(\sigma)} y^{s} . \tag{39.102}
\end{equation*}
$$

Ref. [3] calculates the mean and variance of estimator $\widehat{A T T}$. The mean is biased, but one can define a new bias-corrected estimator.

### 39.11.3 Positivity

Positivity is defined as the requirement that for all layers $x$,

$$
\begin{equation*}
0<P\left(d^{\sigma}=1 \mid x^{\sigma}=x\right)<1 \tag{39.103}
\end{equation*}
$$

or, equivalently,

$$
\begin{equation*}
P\left(d^{\sigma}=1 \mid x^{\sigma}=x\right)>0 \quad \text { and } \quad P\left(d^{\sigma}=0 \mid x^{\sigma}=x\right)>0 . \tag{39.104}
\end{equation*}
$$

[^23]In other words, for each layer $x$, there is a non-zero probability of being both treated and untreated.

Recall that

$$
\begin{equation*}
\mathcal{Y}_{d \mid \tilde{d}, x}=\sum_{y} y P_{\underline{y}(d) \mid \tilde{d}, \underline{x}}(y \mid \tilde{d}, x) . \tag{39.105}
\end{equation*}
$$

Also recall that the estimator Eq. 39.83) for $A T T_{x}$ divides by $N_{1, x}=P(d=1 \mid x) N_{x}$ and the estimator Eq. $(39.85)$ for $A T U_{\mid x}$ divides by $N_{0, x}=P(d=0 \mid x) N_{x}$. The estimator Eq. 39.81 for $\overline{A T E} E_{\mid x}$ divides by neither $N_{0, x}$ nor $N_{1, x}$ so it is safe.

If positivity is violated, then for some layer $x, \mathcal{Y}_{d \mid \tilde{d}=0, x}$ or $\mathcal{Y}_{d \mid \tilde{d}=1, x}$ is undefined. Furthermore, the estimator $A T T_{\mid x}$ or $A T U_{\mid x}$ is undefined. If $A T T_{x x}$ (or any other treatment effect) can be estimated, one says it is identifiable (i.e., calculable). If Positivity is violated, then either $A T T_{\mid x}$ or $A T U_{\mid x}$ is not identifiable.

When $P\left(d^{\sigma} \mid x^{\sigma}=x\right)$ becomes 0 or 1 for some $x$, the arrow $\underline{x} \rightarrow \underline{d}$ becomes deterministic for some $x$. This situation is the very antithesis of RCTs, wherein the influence exerted by $\underline{x}^{\sigma}$ on $\underline{d}^{\sigma}$ is uniformly random and therefore ignorable. Hence, it is perhaps not too surprising that a violation of positivity makes $A T T$ or $A T U$ non-identifiable.

### 39.12 Propensity Score

It is often the case that the discrete vector $\underline{x}^{\sigma}$ has too many possible values to make matching possible. In such cases, it is convenient to map the space of vectors $\underline{x}^{\sigma}$ to the real line. One very convenient choice for that map is the propensity score, which is defined as

$$
\begin{equation*}
g\left(x^{\sigma}\right)=P\left(d^{\sigma}=1 \mid x^{\sigma}\right) . \tag{39.106}
\end{equation*}
$$

The propensity score is usually approximated by a sigmoid function using logistic regression ${ }^{[5]}$

$$
\begin{equation*}
g\left(x^{\sigma}\right)=\operatorname{sig}\left(\alpha+\beta x^{\sigma}\right) \tag{39.107}
\end{equation*}
$$

To use the propensity score, one replaces the bnet $G_{i m+}$ by the bnet $G_{p s}$ shown in Fig. 39.11. The TPMs, printed in blue, for the 2 nodes of $G_{p s}$ that differ from the nodes of $G_{i m+}$, are as follows:

$$
\begin{gather*}
P\left(g^{\sigma} \mid x^{\sigma}\right)=\delta\left(g^{\sigma}, g\left(x^{\sigma}\right)\right)  \tag{39.108}\\
P\left(d^{\sigma} \mid g^{\sigma}\right)=g^{\sigma} d^{\sigma}+\left(1-g^{\sigma}\right)\left(1-d^{\sigma}\right) \tag{39.109}
\end{gather*}
$$

[^24]

Figure 39.11: Bnet $G_{p s}$ used when doing propensity scoring.

Note that these TPMs are self-consistent because

$$
\begin{align*}
P(d \mid x) & =\sum_{g} P(d \mid g) P(g \mid x)  \tag{39.110}\\
& =g(x) d+[1-g(x)](1-d)  \tag{39.111}\\
& =P(d=1 \mid x) d+[1-P(d=1 \mid x)](1-d)  \tag{39.112}\\
& =P(d \mid x) \tag{39.113}
\end{align*}
$$

We would like to do propensity score strata-matching by matching gstrata instead of x-strata. PO calculations for x -strata matching use the TPMs for $P(d \mid x), P(x)$ and $P(y \mid d, x)$. To do g-strata matching using the same equations, but with $x$ replaced by $g$, we would need to solve for $P(d \mid g), P(g)$ and $P(y \mid d, g)$ in terms of $P(d \mid x), P(x)$ and $P(y \mid d, x)$. We solve for those next.

From the TPMs for $G_{p s}$, one has

$$
\begin{equation*}
P(d \mid g)=g d+(1-g)(1-d) \tag{39.114}
\end{equation*}
$$

and

$$
\begin{equation*}
P(g)=\sum_{x} \overbrace{\delta(g, g(x))}^{P(g \mid x)} P(x) . \tag{39.115}
\end{equation*}
$$

Next, note that

$$
\begin{equation*}
P(y \mid d, g)=\sum_{x} P(y \mid d, x) P(x \mid g) \tag{39.116}
\end{equation*}
$$

so we need to find $P(x \mid g)$. Since

$$
\begin{align*}
P(x \mid g) & =\frac{P(g \mid x) P(x)}{P(g)}  \tag{39.117}\\
& =\frac{\delta(g, g(x)) P(x)}{P(g)} \tag{39.118}
\end{align*}
$$

we finally get

$$
\begin{equation*}
P(y \mid d, g)=\sum_{x} P(y \mid d, x) \frac{\delta(g, g(x)) P(x)}{P(g)} . \tag{39.119}
\end{equation*}
$$

### 39.13 Multi-time PO bnets (Panel Data)

In this section, we will discuss Multi-time PO bnets (MT-PO).
A time-series is a function $f: D \rightarrow \mathbb{R}$ whose domain $D$ is a discrete set. A time-series usually describes a single unit $\sigma$ (i.e., an individual) in a population.

An observational study (or analysis or model) can be cross-sectional or longitudinal. A cross-sectional study collects and analyzes a cross-sectional dataset; i.e., a dataset for a population at a single time. A longitudinal study or panel study collects and analyzes a longitudinal dataset; i.e., a dataset for a population at multiple times. Thus, a longitudinal study consists of one or more time-series.

Let $\mathcal{T}=\left\{t_{0}, t_{1}, \ldots, t_{\text {ntimes }-1}\right\}$. For any time-series $a_{t}: \mathcal{T} \rightarrow \mathbb{R}$, define

$$
\begin{gather*}
E_{t} a_{t}=\frac{1}{\text { ntimes }} \sum_{t \in \mathcal{T}} a_{t}  \tag{39.120}\\
\Delta_{t} a_{t}=a_{t}-E_{t} a_{t}  \tag{39.121}\\
\left\langle a_{t}, b_{t}\right\rangle_{t}=E_{t} \Delta_{t} a_{t} \Delta_{t} b_{t} \tag{39.122}
\end{gather*}
$$

Consider a quantity $a_{t}^{\sigma}$ that is a function of the time $t$ and of the particular unit $\sigma$ in a population. $a_{t}^{\sigma}$ is said to be a fixed (in time) effect if it is $t$-independent. $a_{t}^{\sigma}$ is said to be a homogeneous effect (antonym: heterogeneous effect) if it is $\sigma$-independent. Henceforth, we will avoid using the word "effect" for these, because that word has already been used for something else in PO theory. Instead, we will use the word "quantity".

Fig 39.12 gives an example of a multi-time PO bnet (MT-PO). Note that in this example, $\underline{x}^{\sigma}$ and $\underline{u}^{\sigma}$ are fixed quantities (i.e., they are $t$-independent). $\underline{u}^{\sigma}$ is an unobserved confounder and $\underline{x}^{\sigma}$ is an observed confounder. For convenience and

Figure 39.12: Example of multi-time PO bnet with fixed quantities $\underline{x}^{\sigma}, \underline{u}^{\sigma}$. The 3 nodes $\underline{x}^{\sigma}$ should be identified as a single node. Likewise, the 3 nodes $\underline{u}^{\sigma}$ should be identified as a single node.
simplicity, we will assume linear deterministic TPMs for the internal (i.e., non-root) nodes. The TPMs for the bnet Fig 39.12, printed in blue, are as follows:

$$
\begin{gather*}
P\left(x^{\sigma}\right)=P_{\underline{x}}\left(x^{\sigma}\right)  \tag{39.123}\\
P\left(u^{\sigma}\right)=P_{\underline{u}}\left(u^{\sigma}\right)  \tag{39.124}\\
P\left(y_{t}^{\sigma} \mid d_{t}^{\sigma}, x^{\sigma}, u^{\sigma}\right)=\mathbb{1}\left(y_{t}^{\sigma}=\delta d_{t}^{\sigma}+\beta x^{\sigma}+u^{\sigma}\right)  \tag{39.125}\\
P\left(d_{t+1}^{\sigma} \mid d_{t}^{\sigma}, x^{\sigma}, u^{\sigma}\right)=\mathbb{1}\left(d_{t+1}^{\sigma}=\alpha d_{t}^{\sigma}+\gamma x^{\sigma}+u^{\sigma}\right) \tag{39.126}
\end{gather*}
$$

Taking time averages of the treatment dose and treatment outcome, we get

$$
\begin{gather*}
E_{t} \underline{y}_{t}^{\sigma}=\delta E_{t} \underline{d}_{t}^{\sigma}+\beta \underline{x}^{\sigma}+\underline{u}^{\sigma}  \tag{39.127}\\
E_{t} \underline{d}_{t+1}^{\sigma}=\alpha E_{t} \underline{d}_{t}^{\sigma}+\gamma \underline{x}^{\sigma}+\underline{u}^{\sigma} \tag{39.128}
\end{gather*}
$$

Subtracting the time averages from the quantities being averaged, we get

$$
\begin{gather*}
\Delta_{t} \underline{y}_{t}^{\sigma}=\delta \Delta_{t} \underline{d}_{t}^{\sigma}  \tag{39.129}\\
\Delta_{t} \underline{d}_{t+1}^{\sigma}=\alpha \Delta_{t} \underline{d}_{t}^{\sigma} \tag{39.130}
\end{gather*}
$$

This allows us to find estimators for $\delta$ and $\alpha$ :

$$
\begin{gather*}
E_{\sigma}\left\langle\underline{y}_{t}^{\sigma}, \underline{y}_{t}^{\sigma}\right\rangle_{t}=\delta E_{\sigma}\left\langle\underline{y}_{t}^{\sigma}, \underline{d}_{t}^{\sigma}\right\rangle_{t}  \tag{39.131}\\
\delta=\frac{E_{\sigma}\left\langle\underline{y}_{t}^{\sigma}, \underline{y}_{t}^{\sigma}\right\rangle_{t}}{E_{\sigma}\left\langle\underline{y}_{t}^{\sigma}, \underline{d}_{t}^{\sigma}\right\rangle_{t}}  \tag{39.132}\\
E_{\sigma}\left\langle\underline{d}_{t+1}^{\sigma}, \underline{d}_{t+1}^{\sigma}\right\rangle_{t}=\alpha E_{\sigma}\left\langle\underline{d}_{t+1}^{\sigma}, \underline{d}_{t}^{\sigma}\right\rangle_{t}  \tag{39.133}\\
\alpha=\frac{E_{\sigma}\left\langle\underline{d}_{t+1}^{\sigma}, \underline{d}_{t+1}^{\sigma}\right\rangle_{t}}{E_{\sigma}\left\langle\underline{d}_{t+1}^{\sigma}, \underline{d}_{t}^{\sigma}\right\rangle_{t}} \tag{39.134}
\end{gather*}
$$

As shown in Fig 39.13, subtraction of time averages from each node removes the confounder nodes from the bnet of Fig 39.12 (However, this assumes that the confounders are time independent and that the TPMs for the internal nodes are linear deterministic, two very strong assumptions).

Figure 39.13: time-average-subtracted (TAS) bnet for the bnet of Fig 39.12.

## Chapter 40

## Program evaluation and review technique (PERT)

This chapter is based on Refs. 38] and [76].
PERT diagrams are used for scheduling a project consisting of a series of interdependent activities and estimating how long it will take to finish the project. PERT diagrams were invented by the NAVY in 1958 to manage a submarine project. Nowadays they are taught in many business and management courses.

A PERT diagram is a Directed Acyclic Graph (DAG) with the following properties. (See Fig 40.2 for an example of a PERT diagram). The nodes $\underline{E}_{i}$ for $i=1,2, \ldots$, ne of a PERT diagram are called events. The edges $i \rightarrow j$ of a PERT diagram are called activities. An event represents the starting (kickoff) date of one or more activities. A PERT diagram has a single root node ( $i=1$, start event) and a single leaf node ( $i=n e$, end event).

The PERT diagram user must initially provide a Duration Times (DT) table which gives $\left(D O_{i \rightarrow j}, D P_{i \rightarrow j}, D M_{i \rightarrow j}\right)$ for each activity $i \rightarrow j$, where
$D O_{i \rightarrow j}=$ optimistic duration time of activity $i \rightarrow j$
$D P_{i \rightarrow j}=$ pessimistic duration time of activity $i \rightarrow j$
$D M_{i \rightarrow j}=$ median duration time of activity $i \rightarrow j$
From the DT table, one calculates:
Duration time of activity $i \rightarrow j$

$$
\begin{equation*}
D_{i \rightarrow j}=\frac{1}{6}\left(D O_{i \rightarrow j}+D P_{i \rightarrow j}+4 D M_{i \rightarrow j}\right) \tag{40.1}
\end{equation*}
$$

Duration Variance of activity $i \rightarrow j$

$$
\begin{equation*}
V_{i \rightarrow j}=\left(\frac{D O_{i \rightarrow j}-D P_{i \rightarrow j}}{D M_{i \rightarrow j}}\right)^{2} \tag{40.2}
\end{equation*}
$$

Often, it is convenient to define "dummy" edges with $D_{i \rightarrow j}=0$. That is perfectly fine.

Define:
$T E S_{i}=$ Earliest start time for event $i$
$T L S_{i}=$ Latest start time for event $i$
slack $_{i}=T L S_{i}-T E S_{i}=$ slack for event $i$
$T E F_{i \rightarrow j}=T E S_{i}+D_{i \rightarrow j}=$ Earliest finish time for activity $i \rightarrow j$.
$T L F_{i \rightarrow j}=T L S_{j}-D_{i \rightarrow j}=$ Latest finish time for activity $i \rightarrow j$. See footnote below. 1

A critical path is a directed path (i.e., a chain of connected arrows, all pointing in the same direction) going from the start to the end node, such that slack equals zero at every node visited. In a DAG, the neighbors of a node is the union of its parent and children nodes. A critical path must also have all other nodes as neighbors; i.e, the union of the neighbors of every node in the path plus the nodes in the path itself, equals all nodes in the graph.

GOAL of PERT analysis: The main goal of PERT analysis is to find, based on the data of the DT table, the interval $\left[T E S_{i}, T L S_{i}\right]$ giving a lower and an upper bound to the starting time of each node $i$. Another goal is to find a critical path for the PERT diagram (which represents an entire project). By adding the $D_{i \rightarrow j}$ of each edge of the critical path, one can get the mean value of the total duration of the entire project, and by adding the variances of each edge along the critical path, one can get an estimate of the total variance of the total duration. Knowing the mean and variance of the total duration and assuming a normal distribution, one can predict the probability that the actual duration will deviate by a certain amount from its mean.

To calculate the interval $\left[T E S_{i}, T L S_{i}\right]$, one follows the following two steps.

1. Assume $T E S_{1}=0$ and solve

$$
\begin{equation*}
T E S_{i}=\max _{a \in p a(i)}(\underbrace{T E S_{a}+D_{a \rightarrow i}}_{T E F_{a \rightarrow i}}) \tag{40.3}
\end{equation*}
$$

for $i \in[2, n e]$. This recursive equation is solved by what is called "forward propagation", wherein one moves up the list of nodes $i$ in order of increasing $i$ starting at $i=1$ with $T E S_{1}=0$.
2. Assume $T L S_{n e}=T E S_{n e}$ and solve

$$
\begin{equation*}
T L S_{i}=\min _{b \in c h(i)}(\underbrace{T L S_{b}-D_{i \rightarrow b}}_{T L F_{i \rightarrow b}}) \tag{40.4}
\end{equation*}
$$

[^25]for $i \in[1, n e-1]$. This recursive equation is solved by what is called "backward propagation", wherein one moves down the list of nodes $i$ in order of decreasing $i$ starting at $i=n e$ with $T L S_{n e}=T E S_{n e} . T E S_{n e}$ is known from step 1.

Eqs. 40.3) and (40.4) are illustrated in Fig 40.1.

Figure 40.1: $T E S_{i}$ defined from info received from parents of $i$ and $T L S_{i}$ defined from info received from children of $i$.

### 40.1 Example

To illustrate PERT analysis, we end with an example. We present the example in the form of an exercise question and then provide the answer. This example comes from Ref.[38], except for part (e) about bnets, which is our own.

Question: For the PERT diagram of Fig 40.2 , calculate the following:
(a) Interval $\left[T E S_{i}, T L S_{i}\right]$ for all $i$.
(b) A critical path for this PERT diagram.
(c) The mean and variance of the total duration of the critical path.
(d) The probability that the total duration will be 225 days or less.
(e) A bnet interpretation of this problem.

Answer to (a) $\left[T E S_{i}, T L S_{i}\right]$ are given by Fig 40.3.
Answer to (b) The critical path is given in red in Fig 40.3. Note that this path does indeed have zero slack at each node it visits and the union of its neighborhood and the path itself encompasses all nodes.

Answer to (c) The mean and variance of the total duration are calculated in Table 40.1.

Answer to (d)

$$
\begin{align*}
P(\underline{x}<225) & =P\left[\frac{\underline{x}-\mu}{\sigma} \leq \frac{225-220}{\sqrt{7.73}}\right]  \tag{40.5}\\
& =P[\underline{z} \leq 1.80]  \tag{40.6}\\
& =0.9641 \tag{40.7}
\end{align*}
$$

Figure 40.2: Example of a PERT diagram. The numbers attached to the arrows are the duration times $D_{i \rightarrow j}$ in days followed by, enclosed in parentheses, the variance $V_{i \rightarrow j}$ of that duration. The info given in this PERT diagram was derived from a DT table in Ref. [38]. The info in this PERT diagram is sufficient for calculating $T E S_{i}$ and $T L S_{i}$ for each node $i$. The results of that calculation are given in Fig.40.3.

$T E S_{i}$ (given after the node name) for node $\underline{E}_{i}$ for all $i$

$T L S_{i}$ (given after the node name) for node $\underline{E}_{i}$ for all $i$

Figure 40.3: Results of calculating $T E S_{i}$ for all $i$ via a forward pass, followed by calculating $T L S_{i}$ for all $i$ via a backward pass. Critical path indicated in red.

Answer to (e) Define 2 bnets.

1. The first PERT bnet is for calculating $T E S_{i}$ for all $i$ and is given by Fig 40.4.

| edge | duration | variance |
| :--- | :--- | :--- |
| $i \rightarrow j$ | $D_{i \rightarrow j}$ | $V_{i \rightarrow j}$ |
| $\mathrm{~A}(1 \rightarrow 2)$ | 50 | 2.56 |
| $\mathrm{D}(2 \rightarrow 5)$ | 60 | 0.44 |
| $\mathrm{G}(5 \rightarrow 7)$ | 30 | 1.78 |
| $\mathrm{~J}(7 \rightarrow 8)$ | 40 | 1.31 |
| $\mathrm{~K}(8 \rightarrow 9)$ | 10 | 0.64 |
| $\mathrm{~L}(9 \rightarrow 10)$ | 30 | 1.00 |
| Total | 220 | 7.73 |

Table 40.1: Calculation of mean and variance of total duration along critical path.

Figure 40.4: bnet for $T E S_{i}$ calculation.
The node TPMs, printed in blue, for the bnet Fig 40.4 are given by (this equation is to be evaluated recursively by a forward pass through the bnet):

$$
\begin{equation*}
P\left(T E S_{i} \mid\left(T E S_{a}\right)_{a \in p a(i)}\right)=\delta\left(T E S_{i}, \max _{a \in p a(i)}\left(T E S_{a}+D_{a \rightarrow i}\right)\right) \tag{40.8}
\end{equation*}
$$

2. The second PERT bnet is for calculating $T L S_{i}$ for all $i$ and is given by Fig.40.5. Note that the directions of all the arrows in the PERT diagram Fig 40.2 have been reversed so Fig 40.5 is a time reversed graph.
The node TPMs, printed in blue, for the bnet Fig 40.5 are given by (this equation is to be evaluate recursively by a backward pass through the bnet):

$$
\begin{equation*}
P\left(T L S_{i} \mid\left(T L S_{b}\right)_{b \in p a(i)}\right)=\delta\left(T L S_{i}, \min _{b \in p a(i)}\left(T L S_{b}-D_{b \rightarrow i}^{T}\right)\right), \tag{40.9}
\end{equation*}
$$

where $D_{i \rightarrow j}^{T}=D_{j \rightarrow i}$.

Figure 40.5: bnet for $T L S_{i}$ calculation.

## Chapter 41

## Recurrent Neural Networks

This chapter is mostly based on Ref. [19].
This chapter assumes you are familiar with the material and notation of Chapter 35 on plain Neural Nets.

Figure 41.1: Simple example of RNN witb $T=3$
Suppose
$T$ is a positive integer.
$t=0,1, \ldots, T-1$,
$\underline{x}_{i}(t) \in \mathbb{R}$ for $i=0,1, \ldots, n u m x-1$,
$\underline{h}_{i}(t) \in \mathbb{R}$ for $i=0,1, \ldots$, numh -1,
$\underline{Y}_{i}(t) \in \mathbb{R}$ for $i=0,1, \ldots$, numy -1,
$W^{h \mid x} \in \mathbb{R}^{\text {numh } \times n u m x}$,
$W^{h \mid h} \in \mathbb{R}^{\text {numh } \times \text { numh }}$,
$W^{y \mid h} \in \mathbb{R}^{\text {numy } \times n u m h}$,
$b^{y} \in \mathbb{R}^{n u m y}$,
$b^{h} \in \mathbb{R}^{\text {numh }}$.
Henceforth, $x(\cdot)$ will mean the array of $x(t)$ for all $t$.

The simplest kind of recurrent neural network (RNN) has the bnet Fig. 41.1 with arbitrary $T$. The node TPMs, printed in blue, for this bnet, are as follows.

$$
\begin{gather*}
P(x(\cdot))=\text { given }  \tag{41.1}\\
P(x(t))=\delta\left(x(t),[x(\cdot)]_{t}\right)  \tag{41.2}\\
P(h(t) \mid h(t-1), x(t))=\delta\left(h(t), \mathcal{A}\left(W^{h \mid x} x(t)+W^{h \mid h} h(t-1)+b^{h}\right)\right), \tag{41.3}
\end{gather*}
$$

where $h(-1)=0$.

$$
\begin{equation*}
P(Y(t) \mid h(t))=\delta\left(Y(t), \mathcal{A}\left(W^{y \mid h} h(t)+b^{y}\right)\right) \tag{41.4}
\end{equation*}
$$

Define

$$
\begin{equation*}
W^{h}=\left[W^{h \mid x}, W^{h \mid h}, b^{h}\right], \tag{41.5}
\end{equation*}
$$

and

$$
\begin{equation*}
W^{y}=\left[W^{y \mid h}, b^{y}\right] . \tag{41.6}
\end{equation*}
$$

The bnet of Fig. 41.1 can be used for classification once its parameters $W^{h}$ and $W^{y}$ have been optimized. To optimize those parameters via gradient descent, one can use the bnet of Fig 41.2.

Let $\sigma=0,1, \ldots, n \operatorname{sam}(\vec{x})-1$ be the labels for a minibatch of samples. The node TPMs, printed in blue, for bnet Fig.41.2, are as follows.

$$
\begin{gather*}
P(x(\cdot)[\sigma])=\text { given }  \tag{41.7}\\
P(x(t)[\sigma])=\delta\left(x(t)[\sigma],[x(\cdot)]_{t}[\sigma]\right) \tag{41.8}
\end{gather*}
$$

$$
\begin{equation*}
P(h(t)[\sigma] \mid h(t-1)[\sigma], x(t)[\sigma])=\delta\left(h(t)[\sigma], \mathcal{A}\left(W^{h \mid x} x(t)[\sigma]+W^{h \mid h} h(t-1)[\sigma]+b^{h}\right)\right. \tag{41.9}
\end{equation*}
$$

$$
\begin{equation*}
P(Y(t)[\sigma] \mid h(t-1)[\sigma])=\delta\left(Y(t)[\sigma], \mathcal{A}\left(W^{y \mid h} h(t-1)[\sigma]+b^{y}\right)\right. \tag{41.10}
\end{equation*}
$$

Figure 41.2: RNN bnet used to optimize parameters $W^{h}$ and $W^{y}$ of RNN bnet Fig 41.1.

$$
\begin{gather*}
P(y(\cdot)[\sigma] \mid x(\cdot)[\sigma])=\text { given }  \tag{41.11}\\
P(\mathcal{E}(t) \mid \vec{y}(\cdot), \vec{Y}(t))=\frac{1}{n \operatorname{sam}(\vec{x})} \sum_{\sigma} d(y(t)[\sigma], Y(t)[\sigma]), \tag{41.12}
\end{gather*}
$$

where

$$
\begin{equation*}
d(y, Y)=|y-Y|^{2} . \tag{41.13}
\end{equation*}
$$

If $y, Y \in[0,1]$, one can use this instead

$$
\begin{gather*}
d(y, Y)=X E(y \rightarrow Y)=-y \ln Y-(1-y) \ln (1-Y)  \tag{41.14}\\
P\left(\mathcal{E} \mid[\mathcal{E}(t)]_{\forall t}\right)=\delta\left(\mathcal{E}, \sum_{t} \mathcal{E}(t)\right) \tag{41.15}
\end{gather*}
$$

For $a=h, y$,

$$
\begin{equation*}
P\left(W^{a}\right)=\text { given } . \tag{41.16}
\end{equation*}
$$

The first time it is used, $W^{a}$ is fairly arbitrary. Afterwards, it is determined by previous horizontal stage.

$$
\begin{equation*}
P\left(\left(W^{a}\right)^{\prime} \mid \mathcal{E}, W^{a}\right)=\delta\left(\left(W^{a}\right)^{\prime}, W^{a}-\eta^{a} \partial_{W^{a}} \mathcal{E}\right) \tag{41.17}
\end{equation*}
$$

$\eta^{a}>0$ is the learning rate for $W^{a}$.

### 41.1 Language Sequence Modeling

Figs 41.1, and 41.2 with arbirary $T$ can be used as follows to do Language Sequence Modeling.

For this usecase, one must train with the following TPM for node $\vec{y}(\cdot)$ :

$$
\begin{equation*}
P(y(\cdot)[\sigma] \mid x(\cdot)[\sigma])=\prod_{t} \mathbb{1}\left(y(t)[\sigma]=P\left(x(t)[\sigma] \mid\left[x\left(t^{\prime}\right)[\sigma]\right]_{t^{\prime}<t}\right)\right) \tag{41.18}
\end{equation*}
$$

With such training, one gets

$$
\begin{equation*}
P(Y(t) \mid h(t))=\mathbb{1}\left(\quad Y(t)=P\left(x(t) \mid\left[x\left(t^{\prime}\right)\right]_{t^{\prime}<t}\right)\right) . \tag{41.19}
\end{equation*}
$$

Therefore,

$$
\begin{gather*}
Y(0)=P(x(0)),  \tag{41.20}\\
Y(1)=P(x(1) \mid x(0)),  \tag{41.21}\\
Y(2)=P(x(2) \mid x(0), x(1)), \tag{41.22}
\end{gather*}
$$

and so on.
We can use this to:

- predict the probability of a sentence, example: Get $P(x(0), x(1), x(2))$.
- predict the most likely next word in a sentence,
example: Get $P(x(2) \mid x(0), x(1))$.
- generate fake sentences.
example:
Get $x(0) \sim P(x(0))$.
Next get $x(1) \sim P(x(1) \mid x(0))$.
Next get $x(2) \sim P(x(2) \mid x(0), x(1))$.

### 41.2 Other types of RNN

Figure 41.3: RNN bnet of the many to many kind. This one can be used for translation. $x(0)$ and $x(1)$ might denote two words of an English sentence, and $Y(2)$ and $Y(3)$ might be their Italian translation.

Let $\mathcal{T}=\{0,1, \ldots, T-1\}$, and $\mathcal{T}^{x}, \mathcal{T}^{y} \subset \mathcal{T}$. Above, we assumed that $\underline{x}(t)$ and $\underline{Y}(t)$ were both defined for all $t \in \mathcal{T}$. More generally, they might be defined only for subsets of $\mathcal{T}: \underline{x}(t)$ for $t \in \mathcal{T}^{x}$ and $\underline{Y}(t)$ for $t \in \mathcal{T}^{y}$. If $\left|\mathcal{T}^{x}\right|=1$ and $\left|\mathcal{T}^{y}\right|>1$, we say the RNN bnet is of the 1 to many kind. In general, can have $\mathbf{1}$ to $\mathbf{1}, \mathbf{1}$ to many, many to 1 , many to many RNN bnets.

Plain RNNs can suffer from the vanishing or exploding gradients problem. There are various ways to mitigate this (good choice of initial $W^{h}$ and $W^{y}$, good choice of activation functions, regularization). Or by using GRU or LSTM (discussed below). GRU and LSTM were designed to mitigate the vanishing or exploding gradients problem. They are very popular in NLP (Natural Language Processing).

### 41.2.1 Long Short Term Memory (LSTM) unit (1997)

This section is based on Wikipedia article Ref. 65]. In this section, $\odot$ will denote the Hadamard matrix product (elementwise product).

Figure 41.4: bnet for a Long Short Term Memory (LSTM) unit.
Let
$\underline{x}(t) \in \mathbb{R}^{\text {numx }}$ : input vector to the LSTM unit
$\underline{f}(t) \in \mathbb{R}^{\text {numh }}:$ forget gate's activation vector
$\underline{\underline{i}}(t) \in \mathbb{R}^{\text {numh }}$ : input/update gate's activation vector
$\underline{o}(t) \in \mathbb{R}^{\text {numh }}$ : output gate's activation vector
$\underline{h}(t) \in \mathbb{R}^{n u m h}:$ hidden state vector also known as output vector of the LSTM
unit
$\underline{\tilde{c}}(t) \in \mathbb{R}^{\text {numh }}:$ cell input activation vector
$\underline{c}(t) \in \mathbb{R}^{\text {numh }}:$ cell state vector
$\underline{Y}(t) \in \mathbb{R}^{\text {numy }}:$ classification of $x(t)$.
$W \in \mathbb{R}^{\text {numh } \times \text { numx }}, U \in \mathbb{R}^{\text {numh } \times n u m h}$ and $b \in \mathbb{R}^{\text {numh }}$ : weight matrices and bias
vectors, parameters learned by training.
$\mathcal{W}^{y \mid h} \in \mathbb{R}^{\text {numy } \times \text { numh }}:$ weight matrix
Fig. 41.4 is a bnet net for a LSTM unit. The node TPMs, printed in blue, for this bnet, are as follows.

$$
\begin{equation*}
P(f(t) \mid x(t), h(t-1))=\mathbb{1}\left(\quad f(t)=\operatorname{sig}\left(W^{f \mid x} x(t)+U^{f \mid h} h(t-1)+b^{f}\right)\right) \tag{41.23}
\end{equation*}
$$

where $h(-1)=0$.

$$
\begin{align*}
& P(i(t) \mid x(t), h(t-1))=\mathbb{1}\left(\quad i(t)=\operatorname{sig}\left(W^{i \mid x} x(t)+U^{i \mid h} h(t-1)+b^{i}\right)\right)  \tag{41.24}\\
& P(o(t) \mid x(t), h(t-1))=\mathbb{1}\left(\quad o(t)=\operatorname{sig}\left(W^{o \mid x} x(t)+U^{o \mid h} h(t-1)+b^{o}\right)\right)  \tag{41.25}\\
& P(\tilde{c}(t) \mid x(t), h(t-1))=\mathbb{1}\left(\quad \tilde{c}(t)=\tanh \left(W^{c \mid x} x(t)+U^{c \mid h} h(t-1)+b^{c}\right)\right) \tag{41.26}
\end{align*}
$$

$$
\begin{equation*}
P(c(t) \mid f(t), c(t-1), i(t), \tilde{c}(t))=\mathbb{1}(\quad c(t)=f(t) \odot c(t-1)+i(t) \odot \tilde{c}(t)) \tag{41.27}
\end{equation*}
$$

$$
\begin{equation*}
P(h(t) \mid o(t), c(t))=\mathbb{1}(\quad \quad h(t)=o(t) \odot \tanh (c(t))) \tag{41.28}
\end{equation*}
$$

$$
\begin{equation*}
P(Y(t) \mid h(t))=\mathbb{1}\left(\quad Y(t)=\mathcal{A}\left(\mathcal{W}^{y \mid h} h(t)+b^{y}\right)\right) \tag{41.29}
\end{equation*}
$$

### 41.2.2 Gated Recurrence Unit (GRU) (2014)

This section is based on Wikipedia article Ref.[54]. In this section, $\odot$ will denote the Hadamard matrix product (elementwise product).

GRU is a more recent (17 years later) attempt at simplifying LSTM unit.

Figure 41.5: bnet for a Gated Recurrent Unit (GRU).
Let
$\underline{x}(t) \in \mathbb{R}^{\text {numx }}$ : input vector
$\underline{h}(t) \in \mathbb{R}^{\text {numh }}$ : output vector
$\underline{\hat{h}}(t) \in \mathbb{R}^{\text {numh }}:$ candidate activation vector
$\underline{z}(t) \in \mathbb{R}^{\text {numh }}:$ update gate vector
$\underline{r}(t) \in \mathbb{R}^{\text {numh }}:$ reset gate vector
$\underline{Y}(t) \in \mathbb{R}^{\text {numy }}:$ classification of $x(t)$.
$W \in \mathbb{R}^{\text {numh } \times n u m x}, U \in \mathbb{R}^{\text {numh } \times \text { numh }}$ and $b \in \mathbb{R}^{\text {numh }}$ : weight matrices and bias vectors, parameters learned by training.
$\mathcal{W}^{y \mid h} \in \mathbb{R}^{\text {numy } \times \text { numh }}:$ weight matrix
Fig 41.5 is a bnet net for a GRU. The node TPMs, printed in blue, for this bnet, are as follows.

$$
\begin{equation*}
P(z(t) \mid x(t), h(t-1))=\mathbb{1}\left(\quad z(t)=\operatorname{sig}\left(W^{z \mid x} x(t)+U^{z \mid h} h(t-1)+b^{z}\right)\right), \tag{41.30}
\end{equation*}
$$

where $h(-1)=0$.

$$
\begin{gather*}
P(r(t) \mid x(t), h(t-1))=\mathbb{1}\left(\quad r(t)=\operatorname{sig}\left(W^{r \mid x} x(t)+U^{r \mid h} h(t-1)+b^{r}\right)\right)  \tag{41.31}\\
P(\hat{h}(t) \mid x(t), r(t), h(t-1))=\mathbb{1}\left(\quad \hat{h}(t)=\tanh \left(W^{h \mid x} x(t)+U^{h \mid h}(r(t) \odot h(t-1))+b^{h}\right)\right) \tag{41.32}
\end{gather*}
$$

$$
\begin{equation*}
P(h(t) \mid z(t), h(t-1), \hat{h}(t))=\mathbb{1}(\quad h(t)=(1-z(t)) \odot h(t-1)+z(t) \odot \hat{h}(t)) \tag{41.33}
\end{equation*}
$$

$$
\begin{equation*}
P(Y(t) \mid h(t))=\mathbb{1}\left(\quad Y(t)=\mathcal{A}\left(\mathcal{W}^{y \mid h} h(t)+b^{y}\right)\right) \tag{41.34}
\end{equation*}
$$

## Chapter 42

## Regression Discontinuity Design

This chapter is based on Ref. 3 .
This chapter assumes that the reader has read Chapter 39 on Potential Outcomes (PO).

In Regression Discontinuity Design (RDD), one switches the treatment dose $\underline{d}$ from 0 when $\underline{x}<\xi$ to 1 where $\underline{x}>\xi$, where $\underline{x}$ is an observed confounder (call it the switch confounder) and $\xi$ is a threshold value for $\underline{x}$. One measures the jump $\delta$ in the treatment outcome $\underline{y}$ as $\underline{x}$ passes through $\underline{x}=\xi$. Then one makes the very reasonable assumption that $\delta \underline{\text { equals }}{ }^{1} \mathcal{Y}_{1 \mid x=\xi}-\mathcal{Y}_{0 \mid x=\xi}=A T E_{\mid x=\xi}$ for an imaginary experiment in which the confounder $\underline{x}$ acts as a normal confounder that doesn't switch the treatment dose $d$.

For example, $d^{\sigma}$ might be whether an individual is admitted to Harvard Univ., $y^{\sigma}$ might be how much money the individual earns for the first 20 years after graduating from Harvard, and $x^{\sigma}$ might be his SAT scores. We assume Harvard only admits students with an SAT score higher than $\xi$.

### 42.1 PO analysis

Figure 42.1: 2 bnets used in the PO analysis of RDD. The TPMs for $G_{d i s c}$ are defined in terms of the TPMs for $G$. The TPM $P\left(d^{\sigma} \mid x^{\sigma}\right)$ for $G_{d i s c}$ is discontinuous in $x^{\sigma}$.

[^26]The TPMs, printed in blue, for the bnet $G_{\text {disc }}$ shown in Fig 42.1, are as follows. Note that the TPMs for the bnet $G_{\text {disc }}$ are defined in terms of the TPMs for the bnet $G$.

$$
\begin{gather*}
P\left(x^{\sigma}\right)=\delta\left(x^{\sigma}, x\right)  \tag{42.1}\\
P\left(y^{\sigma} \mid d^{\sigma}, x^{\sigma}=x\right)=P_{\underline{y} \mid \underline{d}, \underline{x}}\left(y^{\sigma} \mid d^{\sigma}, x\right)  \tag{42.2}\\
P\left(d^{\sigma} \mid x^{\sigma}=x\right)= \begin{cases}P_{\underline{d} \mid \underline{x}}\left(d^{\sigma} \mid x^{\sigma}=x\right) & \text { for } x>\xi \\
\delta\left(d^{\sigma}, 0\right) & \text { for } x<\xi\end{cases} \tag{42.3}
\end{gather*}
$$

Define

$$
\begin{equation*}
E_{\sigma \mid x}\left[y^{\sigma}(d)\right]=E_{y \mid x}[\underline{y}(d)]=\mathcal{Y}_{d \mid x} \tag{42.4}
\end{equation*}
$$

and

$$
\begin{equation*}
\xi \pm=\xi \pm \epsilon \tag{42.5}
\end{equation*}
$$

for some infinitesimal $\epsilon>0$.
See Fig.42.2. In RDD, we assume that if we define the following $2 \delta$ 's, one for bnet $G$ and the other for bnet $G_{d i s c}$, then the two $\delta$ 's are equal, and they equal a conditional ATE.

$$
\begin{gather*}
\delta_{G_{d i s c}}=\mathcal{Y}_{1 \mid x=\xi+}-\mathcal{Y}_{0 \mid x=\xi-}  \tag{42.6}\\
\delta_{G}=\mathcal{Y}_{1 \mid x=\xi}-\mathcal{Y}_{0 \mid x=\xi}  \tag{42.7}\\
\delta_{G}=\delta_{G_{d i s c}}=\delta  \tag{42.8}\\
\delta=A T E_{\mid x=\xi} \tag{42.9}
\end{gather*}
$$

### 42.2 Linear Regression

In this section, we show how to apply linear regression (LR) to the PO analysis of RDD.

Figure 42.2: The jump $\delta$ between $\mathcal{Y}_{1 \mid x}$ and $\mathcal{Y}_{0 \mid x}$ is the same for $G$ and $G_{d i s c}$.
$y^{\sigma}$ can be fitted as a function of $x \in \mathbb{R}$, for $d^{\sigma} \in\{0,1\}$, as follows. Here $\epsilon^{\sigma}$ is the residual for individual $\sigma$ and $b_{0}, m_{0}, b_{1}, m_{1} \in \mathbb{R}$ are the fit parameters.

$$
\begin{equation*}
y^{\sigma}=\left[b_{0}+m_{0}(x-\xi)\right]\left(1-d^{\sigma}\right)+\left[b_{1}+m_{1}(x-\xi)\right] d^{\sigma}+\epsilon^{\sigma} . \tag{42.10}
\end{equation*}
$$

Note that Eq. 42.10 yields a straight line in the $y^{\sigma}-x$ plane for $d^{\sigma}=0$, and another straight line for $d^{\sigma}=1$. These 2 lines are colored magenta in Fig.42.2. We are using the standard symbols $b$ to denote the y-intercept, and $m$ to denote the slope of a straight line.

Taking the expected value of Eq. (42.10), we get

$$
\begin{equation*}
\mathcal{Y}_{d \mid x}=\left[b_{0}+m_{0}(x-\xi)\right](1-d)+\left[b_{1}+m_{1}(x-\xi)\right] d \tag{42.11}
\end{equation*}
$$

Hence,

$$
\begin{gather*}
\mathcal{Y}_{1 \mid x=\xi+}=b_{1}, \quad \mathcal{Y}_{0 \mid x=\xi-}=b_{0}  \tag{42.12}\\
\delta=b_{1}-b_{0} \tag{42.13}
\end{gather*}
$$

## Chapter 43

## Reinforcement Learning (RL)

Figure 43.1: Axes for episode time and episode number.
I based this chapter on the following references. Refs. [7] [14]
In RL, we consider an "agent" or robot that is learning.
Let $T \in \mathbb{Z}_{>0}$ be the duration time of an episode of learning. If $T=\infty$, we say that the episode has an infinite time horizon. A learning episode will evolve towards the right, for times $t=0,1, \ldots, T-1$. We will consider multiple learning episodes. The episode number will evolve from top to bottom. This is illustrated in Fig.43.1.

Let $\underline{s}_{t} \in S_{\underline{s}}$ for $t \in[0, T-1]_{\mathbb{Z}}$ be random variables that record the state of the agent at various times $t$.

Let $\underline{a}_{t} \in S_{\underline{a}}$ for $t \in[0, T-1]_{\mathbb{Z}}$ be random variables that record the action of the agent at various times $t$.

Figure 43.2: State-Action-Reward dynamical bnet
Let $\underline{\theta}_{t} \in S_{\underline{\theta}}$ for $t \in[0, T-1]_{\mathbb{Z}}$ be random variables that record the policy parameters at various times $t$.

For $\underline{X} \in\{\underline{s}, \underline{a}, \underline{\theta}\}$, define $\underline{X}$ followed by a dot to be the vector

$$
\begin{equation*}
\underline{X} .=\left[\underline{X}_{0}, \underline{X}_{1}, \ldots, \underline{X}_{T-1}\right] . \tag{43.1}
\end{equation*}
$$

Also let

$$
\begin{equation*}
\underline{X}_{\geq t}=\left[\underline{X}_{t}, \underline{X}_{t+1}, \ldots, \underline{X}_{T-1}\right] . \tag{43.2}
\end{equation*}
$$

Fig 43.2 shows the basic State-Action-Reward bnet for an agent that is learning. The TPMs for the nodes of Fig 43.2 are given in blue below:

$$
\begin{equation*}
P\left(a_{t} \mid s_{t}, \theta_{t}\right)=\text { given } \tag{43.3}
\end{equation*}
$$

$P\left(a_{t} \mid s_{t}, \theta_{t}\right)$ is called a policy with parameter $\theta_{t}$.

$$
\begin{equation*}
P\left(s_{t} \mid s_{t-1}, a_{t-1}\right)=\text { given. } \tag{43.4}
\end{equation*}
$$

$P\left(s_{t} \mid s_{t-1}, a_{t-1}\right)$ is called the TPM of the model. $P\left(s_{t} \mid s_{t-1}, a_{t-1}\right)$ reduces to $P\left(s_{0}\right)$ when $t=0$.

$$
\begin{equation*}
\left.P\left(r_{t} \mid s_{t}, a_{t}\right)=\delta\left(r_{t}, r\left(s_{t}, a_{t}\right)\right)\right) \tag{43.5}
\end{equation*}
$$

$r: S_{\underline{s}} \times S_{\underline{a}} \rightarrow \mathbb{R}$ is a given one-time reward function.
Note that

$$
\begin{equation*}
P(s ., a . \mid \theta .)=\prod_{t=0}^{T-1}\left\{P\left(s_{t} \mid s_{t-1}, a_{t-1}\right) P\left(a_{t} \mid s_{t}, \theta_{t}\right)\right\} \tag{43.6}
\end{equation*}
$$

Define the all times reward $\Sigma$ by

$$
\begin{equation*}
\Sigma(s ., a .)=\sum_{t=0}^{T-1} \gamma^{t} r\left(s_{t}, a_{t}\right) \tag{43.7}
\end{equation*}
$$

Here $0<\gamma<1$. $\gamma$, called the discount rate, is included to assure convergence of $\Sigma$ when $T \rightarrow \infty$. If $r\left(s_{t}, a_{t}\right)<K$ for all $t$, then $\Sigma<K \frac{1}{1-\gamma}$.

Define the objective (i.e. goal) function $E \Sigma(\theta$.$) by$

$$
\begin{equation*}
E \Sigma(\theta .)=E_{\underline{s}, \cdot \underline{a} \cdot \mid \theta .} . \Sigma(\underline{s} ., \underline{a} .)=\sum_{s ., a .} P(s ., a . \mid \theta .) \Sigma(s ., a .) \tag{43.8}
\end{equation*}
$$

The goal of RL is to maximize the objective function over its parameters $\theta$.. The parameters $\theta^{*}$. that maximize the objective function are the optimum strategy:

$$
\begin{equation*}
\theta .^{*}=\underset{\theta .}{\operatorname{argmax}} E \Sigma(\theta .) \tag{43.9}
\end{equation*}
$$

Define a future reward for times $\geq t$ as:

$$
\begin{equation*}
\Sigma_{\geq t}\left(\left(s_{t^{\prime}}, a_{t^{\prime}}\right)_{t^{\prime} \geq t}\right)=\sum_{t^{\prime}=t}^{T-1} \gamma^{t^{\prime}-t} r\left(s_{t^{\prime}}, a_{t^{\prime}}\right) \tag{43.10}
\end{equation*}
$$

Define the following expected conditional future rewards (rewards for times $\geq t$, conditioned on certain quantities having given values):

$$
\begin{align*}
v_{t} & =v\left(s_{t}, a_{t} ; \theta .\right)=E_{\underline{s .}, \underline{a_{\underline{L}}} \mid s_{t}, a_{t}, \theta \cdot \theta}\left[\Sigma_{\geq t}\right]  \tag{43.11}\\
V_{t} & =V\left(s_{t} ; \theta .\right)=E_{\underline{s} ., \underline{\underline{a}} \mid s_{t}, \theta \cdot}\left[\Sigma_{\geq t}\right]=E_{\underline{a}_{t}} \mid s_{t}, \theta .\left[v\left(s_{t}, \underline{a}_{t} ; \theta .\right)\right] \tag{43.12}
\end{align*}
$$

$v$ is usually called $Q$ in the literature. We will refer to $Q$ as $v$ in order to follow a convention wherein an $\underline{a}_{t}$-average changes a lower case letter to an upper case one.

We will sometimes write $v\left(s_{t}, a_{t}\right)$ instead of $v\left(s_{t}, a_{t} ; \theta\right.$. $)$.
Since $E \Sigma_{\geq t}$ only depends on $\theta_{\geq t}, v\left(s_{t}, a_{t} ; \theta.\right)=v\left(s_{t}, a_{t} ; \theta_{\geq t}\right)$, and $V\left(s_{t} ; \theta.\right)=$ $V\left(s_{t} ; \theta_{\geq t}\right)$.

Note that the objective function $E \Sigma$ can be expressed in terms of $v_{0}$ by averaging over its unaveraged parameters:

$$
\begin{equation*}
E \Sigma(\theta .)=E_{\underline{s}_{0}, \underline{a}_{0} \mid \theta_{0}} v\left(\underline{s}_{0}, \underline{a}_{0} ; \theta .\right) \tag{43.13}
\end{equation*}
$$

Define a one-time reward and an expected conditional one-time reward as:

$$
\begin{align*}
r_{t} & =r\left(s_{t}, a_{t}\right)  \tag{43.14}\\
R_{t} & =R\left(s_{t} ; \theta_{t}\right)=E_{\underline{a}_{t} \mid s_{t}, \theta_{t}}\left[r\left(s_{t}, \underline{a}_{t}\right)\right] . \tag{43.15}
\end{align*}
$$

Note that

$$
\begin{align*}
\Sigma_{\geq t} & =r_{t}+\gamma r_{t+1}+\gamma^{2} r_{t+2}+\ldots+\gamma^{T-1-t} r_{t+(T-1-t)}  \tag{43.16}\\
& =r_{t}+\gamma \Sigma_{\geq t+1} ; \tag{43.17}
\end{align*}
$$

If we take $E_{\underline{s} ., \underline{a} . \mid s_{t}, a_{t}, \theta .}$. $\left.\cdot\right]$ of both sides of Eq. 43.17), we get

$$
\begin{equation*}
v_{t}=r_{t}+\gamma E_{\underline{s}_{t+1}, \underline{a}_{t+1} \mid \theta .}\left[v_{t+1}\right] . \tag{43.18}
\end{equation*}
$$

If we take $E_{\underline{s} ., \underline{a} . \mid s_{t}, \theta .}[\cdot]$ of both sides of Eq. 43.17), we get

$$
\begin{equation*}
V_{t}=R_{t}+\gamma E_{\underline{s}_{t+1} \mid \theta \cdot}\left[V_{t+1}\right] . \tag{43.19}
\end{equation*}
$$

Note that

$$
\begin{align*}
\Delta r_{t} & =r_{t}-R_{t}  \tag{43.20}\\
& =r_{t}-\left(V_{t}-\gamma E_{s_{t+1} \mid \theta}\left[V_{t+1}\right]\right)  \tag{43.21}\\
& =r_{t}+\gamma E_{\underline{s}_{t+1} \mid \theta \cdot}\left[V_{t+1}\right]-V_{t} . \tag{43.22}
\end{align*}
$$

Define

$$
\begin{equation*}
\Delta v_{t}=v_{t}-V_{t} . \tag{43.23}
\end{equation*}
$$

Note that

$$
\begin{equation*}
\Delta v_{t}=\Delta r_{t} \tag{43.24}
\end{equation*}
$$

Next, we will discuss 3 RL bnets

- exact RL bnet (exact, assumes policy is known)
- Actor-Critic RL bnet (approximate, assumes policy is known)
- Q function learning RL bnet (approximate, assumes policy is NOT known)

### 43.1 Exact RL bnet

An exact RL bnet is given by Fig. 43.3 .
Fig 43.3 is the same as Fig 43.2 but with more nodes added in order to optimize the policy parameters. Here are the TPMs, printed in blue, for the nodes not already discussed in connection to Fig.43.2.

$$
\begin{gather*}
P\left(\theta_{t} \mid \theta .\right)=\delta\left(\theta_{t},(\theta \cdot)_{t}\right)  \tag{43.25}\\
\forall\left(s_{t}, a_{t}\right): P\left(v_{t}\left(s_{t}, a_{t}\right) \mid r_{t}, v_{t+1}(\cdot), \theta \cdot\right)=\delta\left(v_{t}\left(s_{t}, a_{t}\right), r_{t}+\gamma E_{\left.\underline{s}_{t+1}, a_{t+1} \mid \theta \cdot\left[v_{t+1}\right]\right)}\right.  \tag{43.26}\\
P\left(\theta .^{\prime} \mid \theta ., v_{0}(\cdot)\right)=\delta(\theta^{\prime} ., \theta .+\alpha \partial_{\theta} \cdot \underbrace{E_{s_{0}, a_{0} \mid \theta_{0}} v\left(\underline{s}_{0}, \underline{a}_{0} ; \theta \cdot\right)}_{E \Sigma(\theta \cdot)}) \tag{43.27}
\end{gather*}
$$

Figure 43.3: Exact RL bnet. $v_{t}(\cdot)$ means the array $\left[v_{t}\left(s_{t}, a_{t}\right)\right]_{\forall s_{t}, a_{t}}$ The following arrows are implicit: for all $t$, arrow from $\underline{\theta} . \rightarrow \underline{v}_{t}(\cdot)$. We did not draw those arrows so as not to clutter the diagram.
$\alpha>0$ is called the learning rate. This method of improving $\theta$. is called gradient ascent.

Concerning the gradient of the objective function, note that

$$
\begin{align*}
\partial_{\theta_{t}} E \Sigma(\theta .) & =\sum_{s ., a .} \partial_{\theta_{t}} P(s ., a . \mid \theta .) \Sigma(s ., a .)  \tag{43.28}\\
& =\sum_{s ., a .} P\left(s ., a . \mid \theta_{.}\right) \partial_{\theta_{t}} \ln P(s ., a . \mid \theta .) \Sigma(s ., a .)  \tag{43.29}\\
& =E_{\underline{s ., ~ a . ~} \mid} \mid \theta .\left\{\partial_{\theta_{t}} \ln P\left(a_{t} \mid s_{t}, \theta_{t}\right) \Sigma(s ., a .)\right\} . \tag{43.30}
\end{align*}
$$

If we run the agent $n \operatorname{sam}\left(\vec{s}_{t}\right)$ times and obtain samples $s_{t}[i], a_{t}[i]$ for all $t$ and for $i=0,1, \ldots, n \operatorname{sam}\left(\vec{s}_{t}\right)-1$, we can express this gradient as follows:

$$
\begin{equation*}
\partial_{\theta_{t}} E \Sigma\left(\theta_{.}\right) \approx \frac{1}{n \operatorname{sam}\left(\vec{s}_{t}\right)} \sum_{i} \sum_{t=0}^{T-1} \partial_{\theta_{t}} \ln P\left(a_{t}[i] \mid s_{t}[i], \theta_{t}\right) r\left(s_{t}[i], a_{t}[i]\right) \tag{43.31}
\end{equation*}
$$

The exact RL bnet Fig 43.3 is difficult to use to calculate the optimum parameters $\theta^{*}$.. The problem is that $\underline{s}_{t}$ propagates towards the future and the $\underline{v}_{t}(\cdot)$ propagates towards the past, so we don't have a Markov Chain with a chain link for each $t$ (i.e., a dynamical bnet) in the episode time direction. Hence, people have come up with approximate RL bnets that are doubly dynamical (i.e., dynamical along the episode time and episode number axes.) We discuss some of those approximate RL bnets next.

### 43.2 Actor-Critic RL bnet

For the actor-critic RL bnet, we approximate Eq. 43.31) by

$$
\begin{equation*}
\partial_{\theta_{t}} E \Sigma(\theta .) \approx \frac{1}{\operatorname{nsam}(\vec{s})} \sum_{i} \sum_{t=0}^{T-1} \underbrace{\partial_{\theta_{t}} \ln P\left(a_{t}[i] \mid s_{t}[i], \theta_{t}\right)}_{\text {Actor }} \underbrace{\Delta r_{t}\left(s_{t}[i], a_{t}[i]\right)}_{\text {Critic }} \tag{43.32}
\end{equation*}
$$

The actor-critic RL bnet is given by Fig.43.4. This bnet is approximate and assumes that the policy is known. The TPMs for its nodes are given in blue below.

$$
\begin{gather*}
P\left(\theta_{t}\right)=\text { given }  \tag{43.33}\\
P\left(s_{t}[i] \mid s_{t-1}[i], a_{t-1}[i]\right)=\text { given } \tag{43.34}
\end{gather*}
$$

Figure 43.4: Actor-Critic RL bnet.

$$
\begin{gather*}
P\left(a_{t}[i] \mid s_{t}[i], \theta_{t}\right)=\text { given }  \tag{43.35}\\
P\left(r_{t}[i] \mid s_{t}[i], a_{t}[i]\right)=\delta\left(r_{t}[i], r\left(s_{t}[i], a_{t}[i]\right)\right) \tag{43.36}
\end{gather*}
$$

$r: S_{\underline{s}} \times S_{\underline{a}} \rightarrow \mathbb{R}$ is given.

$$
\begin{equation*}
P\left(\Delta v_{t}[i] \mid s_{t}[i], a_{t}[i], s_{t+1}[i]\right)=\delta\left(\Delta v_{t}[i], r\left(s_{t}[i], a_{t}[i]\right)+\gamma \hat{V}\left(s_{t+1}[i] ; \phi^{\prime}\right)-\hat{V}\left(s_{t}[i]\right) ; \phi\right) . \tag{43.37}
\end{equation*}
$$

$$
\begin{equation*}
P\left(\theta^{\prime} .\right)=\delta\left(\theta^{\prime} ., \theta_{t}+\alpha \partial_{\theta_{t}} \sum_{i} \ln P\left(a_{t}[i] \mid s_{t}[i], \theta_{t}\right) \Delta v_{t}[i]\right) \tag{43.38}
\end{equation*}
$$

$\left.\hat{V}\left(s_{t}[i]\right) ; \phi\right)$ is obtained by curve fitting (see Chapter 4t) using samples $\left(s_{t}[i], a_{t}[i]\right)$ $\forall t, i$ with

$$
\begin{equation*}
y[i]=\sum_{t^{\prime}=t}^{T} r\left(s_{t^{\prime}}[i], a_{t^{\prime}}[i]\right) \tag{43.39}
\end{equation*}
$$

Figure 43.5: Q function learning RL bnet.
and

$$
\begin{equation*}
\hat{y}[i]=\hat{V}\left(s_{t}[i] ; \phi\right) . \tag{43.40}
\end{equation*}
$$

Eq. (43.39) is an approximation because $\left(s_{t^{\prime}}, a_{t^{\prime}}\right)_{t^{\prime}>t}$ are averaged over in the exact expression for $\left.V\left(s_{t}\right) . \hat{V}\left(s_{t+1}[i]\right) ; \phi^{\prime}\right)$ is obtained in the same way as $\left.\hat{V}\left(s_{t}[i]\right) ; \phi\right)$ but with $t$ replaced by $t+1$ and $\phi$ by $\phi^{\prime}$.

### 43.3 Q function learning RL bnet

The Q-function learning RL bnet is given by Fig 43.5. This bnet is approximate and assumes that the policy is NOT known. The TPMs for its nodes are given in blue below. (Remember that $Q=v$ ).

$$
\begin{gather*}
P\left(s_{t} \mid s_{t-1}, a_{t-1}\right)=\text { given }  \tag{43.41}\\
P\left(a_{t} \mid s_{t}, v_{t}(\cdot)\right)=\delta\left(a_{t}, \underset{a}{\operatorname{argmax}} v_{t}\left(s_{t}, a\right)\right)  \tag{43.42}\\
P\left(r_{t} \mid s_{t}, a_{t}\right)=\delta\left(r_{t}, r\left(s_{t}, a_{t}\right)\right) \tag{43.43}
\end{gather*}
$$

$r: S_{\underline{s}} \times S_{\underline{a}} \rightarrow \mathbb{R}$ is given.

$$
\begin{align*}
\forall\left(s_{t}, a_{t}\right): \quad & P\left(v_{t}\left(s_{t}, a_{t}\right) \mid v_{t-1}(\cdot)\right)= \\
& =\delta\left(v_{t}\left(s_{t}, a_{t}\right), r\left(s_{t}, a_{t}\right)+\gamma \max _{a} E_{\underline{s}_{t+1} \mid s_{t}, a_{t}} v_{t-1}\left(\underline{s}_{t+1}, a\right)\right) \tag{43.44}
\end{align*}
$$

Figure 43.6: Q function learning RL bnet. Same as Fig 43.5 but with new arrow passing $s_{t}$ to $Q_{t-1}$.

This value for $v_{t}\left(s_{t}, a_{t}\right)$ approximates $v_{t}=r_{t}+\gamma E_{s_{t+1}, a_{t+1}} v_{t+1}$.
Some people use the bnet of Fig. 43.6) instead of Fig. 43.5 and replace Eq. 43.44) by

$$
\begin{align*}
\forall\left(s_{t}, a_{t}\right): \quad P\left(v_{t}\left(s_{t}, a_{t}\right) \mid s_{t+1}, v_{t-1}(\cdot)\right)= \\
\quad=\delta\left(v_{t}\left(s_{t}, a_{t}\right), r\left(s_{t}, a_{t}\right)+\gamma \max _{a} v_{t-1}\left(s_{t+1}, a\right)\right) . \tag{43.45}
\end{align*}
$$

## Chapter 44

## Reliability Box Diagrams and Fault Tree Diagrams

This chapter is based on Refs. 31] and 41.
In this chapter, we assume that reader is familiar with Boolean Algebra. See the Notational Conventions Chapter Notational Conventions and Preliminaries for a quick review of what we recommend that you know about Boolean Algebra to fully appreciate this chapter.

Figure 44.1: Example of rbox diagram.

Figure 44.2: An ftree diagram equivalent to Fig.44.1. It represents $e=\left(\phi_{1} \wedge \phi_{3}\right) \vee$ $\left(\phi_{2} \wedge \phi_{3}\right)$.

Complicated devices with a large number of components such as airplanes or rockets can fail in many ways. If their performance depends on some components

Figure 44.3: How to map an rbox diagram to a bnet.

Figure 44.4: bnet corresponding the rbox diagram Fig 44.1.
working in series and one of the components in the series fails, this may lead to catastrophic failure. To avert such disasters, engineers use equivalent components connected in parallel instead of in series, thus providing multiple backup systems. They analyze the device to find its weak points and add backup capabilities there. They also estimate the average time to failure for the device.

The two most popular diagrams for finding the failure modes and their rates for large complicated devices are

- rbox diagrams $=$ Reliability Box diagrams. See Fig 44.1 for an example.
- ftree diagrams $=$ Fault Tree Diagrams. See Fig 44.2 for an example.

In an ftree diagram, several nodes might stand for the same component of a physical
device. In an rbox diagram, on the other hand, each node represents a distinct component in a device. Hence, rbox diagrams resemble the device they are addressing whereas ftree diagrams don't. Henceforth, we will refer to this desirable property as physical resemblance.

As we will show below with an example, it is pretty straightforward to translate an rbox to an ftree diagram. Going the other way, translating an ftree to an rbox diagram is much more difficult.

Next we will define a new kind of bnet that we will call a failure bnet that has physical resemblance. Then we will describe a simple method of translating (i.e., mapping) any rbox diagram to a failure bnet. Then we will show how a failure bnet can be used to do all the calculations that are normally done with an rbox or an ftree diagram. In that sense, failure bnets seem to afford all the benefits of both ftree and rbox diagrams.

A failure bnet contains nodes of 5 types, labeled $\underline{b}, \underline{e}, \underline{x}_{i}, \underline{\phi}_{i}$, and $\underline{A}_{i}$. All nodes have only two possible states $S=$ Success $=0, F=$ Failure $=1$.

1. The bnet has a beginning node labeled $\underline{b}$ which is always set to success. The $\underline{b}$ node and the $\underline{\phi}_{i}$ nodes are the only root nodes of the bnet.
2. The bnet has a single leaf node, the end node, labeled $\underline{e}$. $\underline{e}$ is fixed. In rbox diagrams, $\underline{e}=S$ whereas in ftree diagrams, $\underline{e}=F$.
3. $\underline{x}^{n x}=\left(\underline{x}_{0}, \underline{x}_{1}, \ldots, \underline{x}_{n x-1}\right) . \underline{x}_{i} \in\{S, F\}$ for all $i$.

Suppose $\underline{x}_{i}$ has parents $\underline{\phi}_{i}$ and $\underline{a}^{n a}=\left(\underline{a}_{0}, \underline{a}_{1}, \ldots \underline{a}_{n a-1}\right)$. Then the TPM of node $\underline{x}_{i}$ is defined to be

$$
\begin{equation*}
P\left(x_{i} \mid \phi_{i}, a^{n a}\right)=\delta\left(x_{i}, \phi_{i} \vee \vee_{i=0}^{n a-1} a_{i}\right) \tag{44.1}
\end{equation*}
$$

4. For each node $\underline{x}_{i}$, the bnet has a "performance" root node $\underline{\phi}_{i} \in\{0,1\}$ with an arrow pointing from it to $\underline{x}_{i}$ (i.e, $\underline{\phi}_{i} \rightarrow \underline{x}_{i}$ ). For all $i$,

$$
\begin{equation*}
P\left(\phi_{i}\right)=\epsilon_{i} \delta\left(\phi_{i}, F\right)+\bar{\epsilon}_{i} \delta\left(\phi_{i}, S\right) . \tag{44.2}
\end{equation*}
$$

$\epsilon_{i}$ is the failure probability and $\bar{\epsilon}_{i}=1-\epsilon_{i}$ is the success probability. We name the failure probability $\epsilon_{i}$ because it is normally very small. It is usually set to $1-e^{-\lambda_{i} t} \approx \lambda_{i} t$ when $\lambda_{i} t \ll 1$, where $\lambda_{i}$ is the failure rate for node $\underline{x}_{i}$ and $t$ stands for time. The rblock literature usually calls $\overline{\epsilon_{i}}=R_{i}$ the reliability of node $\underline{x}_{i}$, and $\epsilon_{i}=\left(1-R_{i}\right)=F_{i}$ its unreliability.
5. The nodes $\underline{A}_{i} \in\{0,1\}$ are simply AND gates. If $\underline{A}_{i}$ has inputs $\underline{y}^{n y}=\left(\underline{y}_{0}, \underline{y}_{1}, \ldots, \underline{y}_{n y-1}\right)$, then the TPM of $\underline{A}_{i}$ is

$$
\begin{equation*}
P\left(A_{i} \mid y^{n y}\right)=\delta\left(A_{i}, \wedge_{i=0}^{n y-1} y_{i}\right) . \tag{44.3}
\end{equation*}
$$

An instance (instantiation) of a bnet is the bnet with all nodes set to a specific state. A realizable instance (r-instance) of a bnet is one which has non-zero probability.

Fig 44.3 shows how to translate any rbox diagram to a failure bnet. To illustrate this procedure, we translated the rbox diagram Fig 44.1 into the failure bnet Fig 44.4 .

For the failure bnet Fig.44.4, one has:

$$
\begin{align*}
& P(b)=\mathbb{1}(b=0) \\
& P\left(x_{1} \mid \phi_{1}, b\right)=\mathbb{1}\left(x_{1}=\phi_{1} \vee b\right) \\
& P\left(x_{2} \mid \phi_{2}, x_{1}\right)=\mathbb{1}\left(x_{2}=\phi_{2} \vee x_{1}\right)  \tag{44.4}\\
& P\left(x_{3} \mid \phi_{3}, b\right)=\mathbb{1}\left(x_{3}=\phi_{3} \vee b\right) \\
& P\left(A \mid x_{2}, x_{3}\right) e=\mathbb{1}\left(x_{2} \wedge x_{3}\right) \\
& P(e \mid A)=\mathbb{1}(e=A)
\end{align*}
$$

Therefore, all r-instances of this bnet must satisfy

$$
\begin{align*}
e & =\left(\phi_{1} \vee \phi_{2}\right) \wedge \phi_{3}  \tag{44.5}\\
& =\left(\phi_{1} \wedge \phi_{3}\right) \vee\left(\phi_{2} \wedge \phi_{3}\right) . \tag{44.6}
\end{align*}
$$

Eq. (44.6) proves that Fig. 44.2 is indeed a representation of Fig. 44.1 .
Next, we consider r-instances of this bnet for two cases: $e=S$ and $e=F$.

- rblock analysis: $e=S=0$.

Table 44.1 shows the probability of all possible $r$-instances that end in success for the failure bnet Fig 44.4. (These r-instances are the main focus of rblock analysis). The first 4 of those probabilities (those with $\phi_{3}=0$ ) sum to $\bar{\epsilon}_{3}$ so the sum $P(e=S)$ of all 5 is

$$
\begin{equation*}
P(e=S)=\bar{\epsilon}_{3}+\bar{\epsilon}_{1} \bar{\epsilon}_{2} \epsilon_{3}, \tag{44.7}
\end{equation*}
$$

or, expressing it in reliability language in which $\bar{\epsilon}=R$,

$$
\begin{equation*}
P(e=S)=R_{3}+R_{1} R_{2} \bar{R}_{3} . \tag{44.8}
\end{equation*}
$$

- ftree analysis: $e=F=1$.

Table 44.2 shows the probability of all possible r-instances that end in failure for the failure bnet Fig.44.4. (These r-instances are the main focus of ftree analysis). If we set $\epsilon_{i}=\epsilon$ and $\bar{\epsilon}_{i} \approx 1$ for $i=1,2,3$, then the first two of those r-instances have probabilities of $\operatorname{order}\left(\epsilon^{2}\right)$ and the third has probability of $\operatorname{order}\left(\epsilon^{3}\right)$. The two lowest order $\left(\operatorname{order}\left(\epsilon^{2}\right)\right)$ r-instances are called the "minimal

| instance | probability |
| :---: | :---: |
|  | $\bar{\epsilon}_{1} \epsilon_{2} \bar{\epsilon}_{3}$ |
|  | $\epsilon_{1} \bar{\epsilon}_{2} \bar{\epsilon}_{3}$ |
|  | $\epsilon_{1} \epsilon_{2} \bar{\epsilon}_{3}$ |
|  | $\bar{\epsilon}_{1} \bar{\epsilon}_{2} \bar{\epsilon}_{3}$ |
|  | $\bar{\epsilon}_{1} \bar{\epsilon}_{2} \epsilon_{3}$ |

Table 44.1: Probabilities of all possible r-instances with $e=S=0$ for failure bnet Fig 44.4 .

Table 44.2: Probabilities of all possible r-instances with $e=F=1$ for the failure bnet Fig. 44.4.
cut sets" of the ftree. We will have more to say about minimal cut sets later on. For now, just note from Eq. (44.6) that the ftree Fig 44.2 is just the result of joining together with ORs two expressions, one for each of the two minimal cut sets.
More general $\underline{x}_{i}$.
Failure bnets can actually accommodate $\underline{x}_{i}$ nodes of a more general kind than what we first stipulated. Here are some possibilities:

For any $a^{n} \in\{0,1\}^{n}$, let

$$
\begin{equation*}
\operatorname{len}\left(a^{n}\right)=\sum_{i} a_{i} \tag{44.9}
\end{equation*}
$$

## - OR gate

$$
\begin{align*}
P\left(x_{i} \mid \phi_{i}, a^{n a}\right) & =\delta\left(x_{i}, \phi_{i} \vee \vee_{j} a_{j}\right)  \tag{44.10}\\
& =\delta\left(x_{i}, \phi_{i} \vee \mathbb{1}\left(\operatorname{len}\left(a^{n a}\right)>0\right)\right) \tag{44.11}
\end{align*}
$$

- AND gate

$$
\begin{align*}
P\left(x_{i} \mid \phi_{i}, a^{n a}\right) & =\delta\left(x_{i}, \phi_{i} \vee \wedge_{j} a_{j}\right)  \tag{44.12}\\
& =\delta\left(x_{i}, \phi_{i} \vee \mathbb{1}\left(\operatorname{len}\left(a^{n a}\right)=n a\right)\right) \tag{44.13}
\end{align*}
$$

- Fail if least $K$ failures (less than $K$ successes)

$$
\begin{equation*}
P\left(x_{i} \mid \phi_{i}, a^{n a}\right)=\delta\left(x_{i}, \phi_{i} \vee \mathbb{1}\left(\operatorname{len}\left(a^{n a}\right) \geq K\right)\right) \tag{44.14}
\end{equation*}
$$

- Fail if less than $K$ failures (at least $K$ successes)

$$
\begin{equation*}
P\left(x_{i} \mid \phi_{i}, a^{n a}\right)=\delta\left(x_{i}, \phi_{i} \vee \mathbb{1}\left(\operatorname{len}\left(a^{n a}\right)<K\right)\right) \tag{44.15}
\end{equation*}
$$

## - Fail if exactly one failure

$$
\begin{equation*}
P\left(x_{i} \mid \phi_{i}, a^{n a}\right)=\delta\left(x_{i}, \phi_{i} \vee \mathbb{1}\left(\operatorname{len}\left(a^{n a}\right)=1\right)\right) \tag{44.16}
\end{equation*}
$$

This equals an XOR (exclusive OR) gate when $n a=2$.

- General gate
$f:\{0,1\}^{n a} \rightarrow\{0,1\}$

$$
\begin{equation*}
P\left(x_{i} \mid \phi_{i}, a^{n a}\right)=\delta\left(x_{i}, \phi_{i} \vee f\left(a^{n a}\right)\right) \tag{44.17}
\end{equation*}
$$

### 44.1 Minimal Cut Sets

Suppose $x \in\{0,1\}$ and $f:\{0,1\} \rightarrow\{0,1\}$. Then by direct evaluation, we see that

$$
\begin{equation*}
f(x)=[\bar{x} f(0)] \vee[x f(1)] . \tag{44.18}
\end{equation*}
$$

Let

$$
\begin{align*}
& !x=1-x \\
& !^{0} x=x  \tag{44.19}\\
& !^{1} x=!x
\end{align*}
$$

Then Eq. 44.18 can be rewritten as

$$
\begin{equation*}
f(x)=\vee_{a \in\{0,1\}}\left[\left(!^{\bar{a}} x\right) f(a)\right] . \tag{44.20}
\end{equation*}
$$

Now suppose $x^{n} \in\{0,1\}^{n}$ and $f:\{0,1\}^{n} \rightarrow\{0,1\}$. Eq. 44.20) generalizes to

$$
\begin{equation*}
f\left(x^{n}\right)=\vee_{a^{n} \in\{0,1\}^{n}}\left[\prod_{i}\left(!^{\bar{a}_{i}} x_{i}\right) f\left(a^{n}\right)\right] . \tag{44.21}
\end{equation*}
$$

Eq.(44.21) is called an ors-of-ands normal form expansion. There is also an ands-ofors normal form expansion obtained by swapping multiplication and $\vee$ in Eq. (44.21), but we won't need it here.

A cut set is a set of $\phi_{i}$ 's such that if they are all equal to $F$, then $e=F$ for all the r-instances. A minimal cut set is a cut set such that there are no larger cut sets that contain it. From the failure bnet, we can always find a function $f:\{0,1\}^{n x} \rightarrow\{0,1\}$ such that $e=f\left(\phi^{n x}\right)$ for all the r-instances. We did that for our example failure bnet and obtained Eq. (44.6). We can then express $f\left(\phi^{n x}\right)$ as an ors-of-ands expansion to find all the minimal cut sets. The ands terms in that ors-of-ands expansion each gives a different minimal cut set, after some simplification. The ors-ofands expression is not unique and it may be necessary to simplify (using the Boolean Algebra identities given in Chapter Notational Conventions and Preliminaries) to remove those redundancies.

## Chapter 45

## Restricted Boltzmann Machines

In what follows, we will abbreviate "restricted Boltzmann machine' by rebo.
Let
$v \in\{0,1\}^{\text {numv }}$
$h \in\{0,1\}^{\text {numh }}$
$b \in \mathbb{R}^{\text {numv }}$ (mnemonic, $v$ and $b$ sound the same)
$a \in \mathbb{R}^{\text {numh }}$
$W^{v \mid h} \in \mathbb{R}^{n u m v \times n u m h}$
Energy:

$$
\begin{equation*}
E(v, h)=-\left(b^{T} v+a^{T} h+v^{T} W^{v \mid h} h\right) \tag{45.1}
\end{equation*}
$$

Boltzmann distribution:

$$
\begin{equation*}
P(v, h)=\frac{e^{-E(v, h)}}{Z} \tag{45.2}
\end{equation*}
$$

Partition function:

$$
\begin{align*}
& Z= \sum_{v, h} e^{-E(v, h)}=Z\left(a, b, W^{v \mid h}\right)  \tag{45.3}\\
& P(v \mid h)=\frac{e^{b^{T} v+a^{T} h+v^{T} W^{v \mid h} h}}{\sum_{v} e^{b^{T} v+a^{T} h+v^{T} W^{v \mid h} h}}  \tag{45.4}\\
&=\frac{e^{b^{T} v+v^{T} W^{v \mid h} h}}{\sum_{v} e^{b^{T} v+v^{T} W^{v \mid h} h}}  \tag{45.5}\\
&=\prod_{i} \frac{e^{v_{i}\left(b_{i}+\sum_{j} W_{i, j}^{v \mid h} h_{j}\right)}}{\sum_{v_{i}=0,1} e^{v_{i}\left(b_{i}+\sum_{j} W_{i, j}^{v \mid h} h_{j}\right)}}  \tag{45.6}\\
&=\prod_{i} P\left(v_{i} \mid h\right)  \tag{45.7}\\
& P\left(v_{i} \mid h\right)=\frac{e^{v_{i}\left(b_{i}+\sum_{j} W_{i, j}^{v \mid h} h_{j}\right)}}{Z_{i}(h)} \tag{45.8}
\end{align*}
$$

Figure 45.1: bnet for a Restricted Boltzmann Machine (rebo) with numv $=3$

Eq. 45.8 implies that a rebo can be represented by the bnet Fig. 45.1 .
Let

$$
\begin{equation*}
x_{i}=b_{i}+\sum_{j} W_{i j}^{v \mid h} h_{j} . \tag{45.9}
\end{equation*}
$$

Then

$$
\begin{align*}
P\left(v_{i}=1 \mid h\right) & =\frac{e^{x_{i}}}{1+e^{x_{i}}}  \tag{45.10}\\
& =\frac{1}{1+e^{-x_{i}}}  \tag{45.11}\\
& =\operatorname{sig}\left(x_{i}\right) \tag{45.12}
\end{align*}
$$

One could also expand the node $\underline{h}$ in Fig 45.1 into numh nodes. But note that $P(h) \neq \prod_{j} P\left(h_{j}\right)$ so there would be arrows among the $h_{j}$ nodes.

Note that the rebo bnet is a special case of Naive Bayes (See Chapter 34) with $v_{i}, h_{i} \in\{0,1\}$ and specific $P(h)$ and $P\left(v_{i} \mid h\right)$ node matrices.

## Chapter 46

## ROC curves

This chapter is based on Ref. [77].
ROC stands for Receiver Operating Characteristic. ROC curves are used in binary classification (BC).

To do BC, we are given the value $x \in \mathbb{R}$ for an individual. From this, we want to decide whether that individual has $a=T=$ True or $a=F=$ False. The decision will depend on the value of a threshold parameter $\tau \in \mathbb{R}$.

$$
\underline{x} \longleftarrow \underline{a}
$$

Figure 46.1: bnet for BC.
Fig 46.1 shows the bnet used for BC.

Figure 46.2: $x$-distribution for two hypotheses $a=F, T$.

Fig 46.2 is a plot of $P(x \mid a)$, i.e., the TPM for node $\underline{x}$ of the bnet in Fig 46.1. Whereas $a$ is binary, $x$ is continuous. But we can replace $x$ by a binary variable

$$
\begin{equation*}
b=\mathbb{1}(x>\tau) . \tag{46.1}
\end{equation*}
$$

$P(b \mid a)$ for $b \in\{0,1\}$ and $a \in\{F, T\}$ is called the confusion matrix or contingency table for BC. The confusion matrix can be calculated from the TPM $P(x \mid a)$. Fig. 46.3 illustrates the confusion matrix $P(b \mid a)$ for BC. In that figure, the rates $R$ are defined as follows.

|  |  | Actual Value (a) |  |
| :--- | :---: | :---: | :---: |
|  |  | False | True |
| Predicted <br> Value (x) | Negative | $R_{F N} \mathbf{\Delta}$ | $R_{T N} \wedge$ |
|  | Positive | $R_{F P} \Omega$ | $R_{T P} \wedge$ |

Figure 46.3: The confusion matrix $P(b \mid a)$ for BC.

- False Positive rate

$$
\begin{equation*}
R_{F P}(\tau)=P(x>\tau \mid a=F)=\int_{x>\tau} d x P(x \mid a=F) \tag{46.2}
\end{equation*}
$$

In Hypothesis Testing, $R_{F P}$ is also called the p-value that $\underline{x}>\tau$ assuming curve $F$ is the null hypothesis.

- False Negative rate

$$
\begin{align*}
R_{F N}(\tau) & =1-R_{F P}(\tau)  \tag{46.3}\\
& =P(x<\tau \mid a=F)=\int_{x<\tau} d x P(x \mid a=F) \tag{46.4}
\end{align*}
$$

- True Positive rate

$$
\begin{equation*}
R_{T P}(\tau)=P(x>\tau \mid a=T)=\int_{x>\tau} d x P(x \mid a=T) \tag{46.5}
\end{equation*}
$$

In Hypothesis Testing, $R_{T P}$ is called the p-value that $\underline{x}>\tau$ assuming curve $T$ is the null hypothesis.

- True Negative rate

$$
\begin{align*}
R_{T N}(\tau) & =1-R_{T P}(\tau)  \tag{46.6}\\
& =P(x<\tau \mid a=T)=\int_{x<\tau} d x P(x \mid a=T) \tag{46.7}
\end{align*}
$$

The Receiver Operating Characteristic (ROC) is a parametric plot with $X=R_{F P}(\tau)$ and $Y=R_{T P}(\tau)$, where $\tau \in \mathbb{R}$. The Area Under the Curve (AUC) is the area under the ROC. Fig. 46.4 shows an example of a ROC and its AUC.

Fig 46.5 shows situations that give $\mathrm{AUC}=.5$ (random classifier), $\mathrm{AUC}=.85$, and $\mathrm{AUC}=1$ (perfect classifier). It's also possible to get an $A U C \in[0,0.5]$, but we will ignore those models becauses they are useless for BC.

Note that

Figure 46.4: Example of ROC. Green shaded area is the AUC of the ROC.

Figure 46.5: ROC curves for 3 different separations between the $T$ and $F \mathrm{x}$ distributions.

$$
\begin{align*}
A U C & =\int_{x=0}^{1} d \tau \quad R_{T P}(\tau) \frac{d R_{F P}(\tau)}{d \tau}  \tag{46.8}\\
& =\int_{\infty}^{\infty} d \tau\left\{\int_{-\infty}^{\infty} d x \mathbb{1}(x>\tau) P(x \mid a=T)\right\}(-1) P(x=\tau \mid a=F)(46.9) \\
& =\int_{-\infty}^{\infty} d x^{\prime} \int_{-\infty}^{\infty} d x \mathbb{1}\left(x>x^{\prime}\right) P(x \mid a=T) P\left(x^{\prime} \mid a=F\right) \tag{46.10}
\end{align*}
$$

## Chapter 47

## Scoring the Nodes of a Learned Bnet

Chapter 49 discusses how to learn a bnet from data. Many algorithms for doing this require scoring how well a particular bnet fits the data. This chapter is an introduction to such scoring.

Normally, each node of a bnet is scored separately, and then those node scores are summed to get the bnet score.

In this chapter, scores are defined so that a higher score means a better fit. By taking the negative of such a score, one can always get a score such that a lower score means a better fit.

There are 2 main types of bnet scores: Maximum Likelihood (ML) scores, and Shannon Information Theory (SIT) scores. ML scores consist of the log of a maximum likelihood function $P(\vec{x} \mid \theta)$ for i.i.d. samples $\vec{x}=(x[\sigma])_{\sigma=0,1, \ldots, n s a m-1}$, where $x[\sigma] \sim P_{\underline{x} \mid \theta}(x \mid \theta):$

$$
\begin{align*}
\text { ML-score } & =\ln (P(\vec{x} \mid \theta))  \tag{47.1}\\
& =\ln \prod_{\sigma} P(x[\sigma] \mid \theta)  \tag{47.2}\\
& =\sum_{\sigma} \ln P(x[\sigma] \mid \theta)  \tag{47.3}\\
& \approx \operatorname{nam} \sum_{x} P(x \mid \theta) \ln P(x \mid \theta)  \tag{47.4}\\
& =-n \operatorname{sam} H\left(P_{\underline{x} \mid \theta}\right), \tag{47.5}
\end{align*}
$$

and SIT scores consist of a negative entropy:

$$
\begin{equation*}
\text { Info-score }=-H\left(P_{\underline{x} \mid \theta}\right) \tag{47.6}
\end{equation*}
$$

Thus, up to a factor of nsam, they are the same thing. Maximizing a log likelihood function for i.i.d. samples or minimizing the corresponding entropy, are the same
thing, and they both yield a good estimate of the hidden parameters $\theta$.

### 47.1 Probability Distributions and Special Functions

While writing this chapter, I briefly consulted the following Wikipedia articles about the definitions and properties of certain probability distributions and special functions.

- Categorical Distribution, Ref.[47]
- Multinomial Distribution, Ref. 70
- Dirichlet Distribution, Ref. 50
- Multivariate Normal Distribution, Ref.[72]
- Beta function, Ref. 44]
- Multinomial Coefficients, Ref. [71]
- Gamma Function Ref. 53 ]

Here are a few results from those Wikipedia articles that we will use later on in this chapter.

Below, we will abbreviate $q_{+}=\sum_{i} q_{i}$, and $q .=\left(q_{0}, q_{1}, \ldots, q_{n q-1}\right)$ for various quantities $q$

Gamma function. If $n>0$ is an integer,

$$
\begin{equation*}
\Gamma(n+1)=n! \tag{47.7}
\end{equation*}
$$

The multivariate Beta function is defined by

$$
\begin{equation*}
B(\alpha .)=\frac{\prod_{k} \Gamma\left(\alpha_{k}\right)}{\Gamma\left(\alpha_{+}\right)} \tag{47.8}
\end{equation*}
$$

where $\alpha_{k}>0$ for all $k$.
The multinomial coefficient is defined by

$$
\begin{equation*}
C(N .)=\frac{N_{+}!}{\prod_{k} N_{k}!} \tag{47.9}
\end{equation*}
$$

where $N_{k}$ are non-negative integers.
The inverse of the multinomial coefficient will be denoted by

$$
\begin{equation*}
C I(N .)=\frac{1}{C(N .)}=\frac{\prod_{k} N_{k}!}{N_{+}!} \tag{47.10}
\end{equation*}
$$

The Categorical Distribution is defined by

$$
\begin{equation*}
\operatorname{Cat}(x ; \pi .)=\pi_{x}=\prod_{k} \pi_{k}^{\mathbb{1}(k=x)} \tag{47.11}
\end{equation*}
$$

for $k, x \in S_{\underline{x}}$, where $\pi$. is a probability dist.(i.e., $\pi_{k} \geq 0$ for all $k$, and $\pi_{+}=1$ ).
The Multinomial Distribution is defined by

$$
\begin{equation*}
\operatorname{Mul}(N . ; \pi ., N)=C(N .) \tag{47.12}
\end{equation*}
$$

where $N_{k}$ is a non-negative integer for all $k, N_{+}=N$, and $\pi$. is a probability dist. $\operatorname{Mul}()$ satisfies:

$$
\begin{equation*}
E\left[N_{k}\right]=N \pi_{k} . \tag{47.13}
\end{equation*}
$$

The Dirichlet Distribution is defined by

$$
\begin{equation*}
\operatorname{Dir}(\pi . ; \alpha .)=\frac{1}{B(\alpha .)} \prod_{k} \pi_{k}^{\alpha_{k}-1} \tag{47.14}
\end{equation*}
$$

where $\alpha_{k}>0$ for all $k$, and $\pi$. is a probability dist. The $\alpha$. are called concentration parameters or hyperparameters. Dir() satisfies:

$$
\begin{equation*}
E\left[\underline{\pi_{k}}\right]=\frac{N_{k}}{N_{+}} . \tag{47.15}
\end{equation*}
$$

$\overline{\operatorname{Dir}()}$ is conjugate prior of Mul()
Note that

$$
\begin{equation*}
\operatorname{Mul}\left(N_{.} ; \pi ., N\right) \operatorname{Dir}(\pi . ; \alpha .)=\mathcal{K}(N ., \alpha .) \operatorname{Dir}(\pi . ; N .+\alpha .), \tag{47.16}
\end{equation*}
$$

where

$$
\begin{equation*}
\mathcal{K}\left(N_{.}, \alpha .\right)=\frac{B(N .+\alpha .)}{C I(N .) B(\alpha .)} \tag{47.17}
\end{equation*}
$$

$\overline{\operatorname{Dir}()}$ is replaceable by a $\operatorname{Mul}()$ for large concentration parameters
Note that if $N_{k}$ is a positive integer and $\alpha_{k}=N_{k}+1$ for all $k$, then

$$
\begin{align*}
\operatorname{Dir}\left(\pi . ; \alpha_{k}=N_{k}+1\right) & =C\left(N_{.}\right) \prod_{k} \pi_{k}^{N_{k}}  \tag{47.18}\\
& =\operatorname{Mul}\left(N_{.} ; \pi ., N_{+}\right) . \tag{47.19}
\end{align*}
$$

### 47.2 Single node with no parents

In this section, we consider a learned bnet consisting of a single node with no parents. We will consider arbitrary learned bnets in the next section. But we start with this simplified case so as to reduce the number of indices in most quantities from 3 to 1 . All the results that we derive in this section will be used in the next section after adding the extra indices. This way, we will avoid carrying the extra indices throughout the intermediate steps of many derivations.

For state $k \in\{0,1, \ldots, n k-1\}$ of a single node $\underline{x}$, let
$\underline{N}_{k}=$ current count number (an integer, data)
$\underline{\pi} .=$ a probability dist, the TPM for the node
$\underline{\alpha}_{k}=$ prior count number

$$
\underline{N} . \longleftarrow \underline{\pi} . \longleftarrow \underline{\alpha} .
$$

Figure 47.1: For a bnet consisting of a single node with no parents, this is a Markov chain of current counts $(\underline{N}$.$) , TPM (\underline{\pi})$, and prior counts $(\underline{\alpha}$.$) .$

Consider the Markov chain bnet of Fig. 47.1, with the following TPMs, given in blue.

$$
\begin{gather*}
P(N . \mid \pi .)=\operatorname{Mul}\left(N . ; \pi ., N_{+}\right)  \tag{47.20}\\
P(\pi . \mid \alpha .)=\operatorname{Dir}(\pi . ; \alpha .) \tag{47.21}
\end{gather*}
$$

It follows that

$$
\begin{align*}
P(N ., \pi . \mid \alpha .) & =P(N . \mid \pi .) P(\pi . \mid \alpha .)  \tag{47.22}\\
& =\operatorname{Mul}\left(N . ; \pi ., N_{+}\right) \operatorname{Dir}(\pi . ; \alpha .)  \tag{47.23}\\
& =\mathcal{K}(N ., \alpha .) \operatorname{Dir}(\pi . ; N .+\alpha .) . \tag{47.24}
\end{align*}
$$

From Eq. 47.15) for the expected value of $\operatorname{Dir}()$, we get

$$
\begin{equation*}
\hat{\pi} .=E[\underline{\pi} \cdot]=\frac{N_{.}+\alpha .}{N_{+}+\alpha_{+}} . \tag{47.25}
\end{equation*}
$$

Integrating both sides of Eq. (47.24) over $\pi$., we find that

$$
\begin{equation*}
P(N . \mid \alpha .)=\mathcal{K}\left(N_{.}, \alpha .\right) . \tag{47.26}
\end{equation*}
$$

If $N_{k} \gg 1$ for all $k$, then the $\operatorname{Dir}()$ in Eq. (47.24) can be replaced by a $\operatorname{Mul}()$

$$
\begin{equation*}
P\left(N_{.,}, \pi . \mid \alpha .\right) \approx \mathcal{K}\left(N_{.}, \alpha_{.}\right) \operatorname{Mul}\left(N_{.}+\alpha . ; \pi ., N_{+}+\alpha_{+}\right) . \tag{47.27}
\end{equation*}
$$

Therefore,

$$
\begin{align*}
P(N . \mid \pi ., \alpha .) & =\frac{P(N ., \pi . \mid \alpha .)}{P(N . \mid \alpha .)}  \tag{47.28}\\
& =\operatorname{Mul}\left(N .+\alpha . ; \pi ., N_{+}+\alpha_{+}\right) \tag{47.29}
\end{align*}
$$

## Claim 27

$$
\begin{align*}
\ln P(N . \mid \hat{\pi} ., \alpha .) & =-\left(N_{+}+\alpha_{+}\right) H\left(\frac{N .+\alpha .}{N_{+}+\alpha_{+}}\right)+\ln C(N .+\alpha .)  \tag{47.30}\\
& >-\left(N_{+}+\alpha_{+}\right) H\left(\frac{N .+\alpha .}{N_{+}+\alpha_{+}}\right)-\frac{1}{2}(n k-1) \ln N_{+} \tag{47.31}
\end{align*}
$$

## proof:

$$
\begin{align*}
\ln P\left(N . \mid \hat{\pi}_{.,}, \alpha .\right) & =\sum_{k}\left(N_{k}+\alpha_{k}\right) \ln \hat{\pi}_{k}+\ln C(N .+\alpha .)  \tag{47.32}\\
& =\sum_{k}\left(N_{k}+\alpha_{k}\right) \ln \frac{N_{k}+\alpha_{k}}{N_{+}+\alpha_{+}}+\ln C(N .+\alpha .)  \tag{47.33}\\
& =-\left(N_{+}+\alpha_{+}\right) H\left(\frac{N .+\alpha .}{N_{+}+\alpha_{+}}\right)+\ln C(N .+\alpha .) \tag{47.34}
\end{align*}
$$

Recall Stirling's approximation of a factorial, valid for large integers $n$ :

$$
\begin{equation*}
\ln n!\approx\left(n+\frac{1}{2}\right) \ln n-n \tag{47.35}
\end{equation*}
$$

Assume $N_{k} \gg 1$ for all $k$. Applying Stirling's approximation to all factorials in $C(N)$, we get

$$
\begin{align*}
\ln C(N .) & \approx\left(N_{+}+\frac{1}{2}\right) \ln N_{+}-N_{+}-\sum_{k}\left[\left(N_{k}+\frac{1}{2}\right) \ln N_{k}-N_{k}\right]  \tag{47.36}\\
& =\left(N_{+}+\frac{1}{2}\right) \ln N_{+}-\sum_{k}\left(N_{k}+\frac{1}{2}\right) \ln N_{k} \tag{47.37}
\end{align*}
$$

Next assume that

$$
\begin{equation*}
N_{k} \approx \frac{N_{+}}{n k} \tag{47.38}
\end{equation*}
$$

Then

$$
\begin{align*}
\ln C(N .) & =\left(N_{+}+\frac{1}{2}\right) \ln N_{+}-n k\left(\frac{N_{+}}{n k}+\frac{1}{2}\right)\left[\ln N_{+}-\ln n k\right]  \tag{47.39}\\
& =-\frac{1}{2}(n k-1) \ln N_{+}+\left(N_{+}+\frac{n k}{2}\right) \ln n k  \tag{47.40}\\
& >-\frac{1}{2}(n k-1) \ln N_{+} . \tag{47.41}
\end{align*}
$$

## QED

### 47.3 Multiple nodes with any number of parents

In the previous section, we considered a bnet consisting of a single node with no parents, so we only needed a single index $k$ for the states of the single node. In this section, we consider an arbitrary bnet with multiple nodes each of which may have multiple parents. Most of the results in the previous section are valid for the general case if we make the following replacements: $\pi . \rightarrow \pi_{\cdot \mid \mu}^{i} N . \rightarrow N_{\cdot, \mu}^{i} \alpha . \rightarrow \alpha_{\cdot, \mu}^{i}$. Upon this replacement, Fig 47.1 becomes Fig 47.2. The TPMs, printed in blue, of the new Markov chain, are as follows:

Figure 47.2: Generalization of Fig 47.1. For a bnet with multiple nodes each of which may have multiple parents, this is a Markov chain of current counts $\left(N_{+, \mu}^{i}\right)$, TPM $\left(\underline{\pi_{\cdot \mid \mu}^{i}}\right)$, and prior counts $\left(\underline{\alpha_{\cdot, \mu}^{i}}\right)$.

$$
\begin{gather*}
P\left(N_{\cdot, \mu}^{i} \mid \pi_{\cdot \mid \mu}^{i}\right)=\operatorname{Mul}\left(N_{\cdot, \mu}^{i} ; \pi_{\cdot \mid \mu}^{i}, N_{+, \mu}^{i}\right)  \tag{47.42}\\
P\left(\pi_{\cdot \mid \mu}^{i} \mid \alpha_{\cdot, \mu}^{i}\right)=\operatorname{Dir}\left(\pi_{\cdot \mid \mu}^{i} ; \alpha_{\cdot, \mu}^{i}\right) \tag{47.43}
\end{gather*}
$$

In these TPMs,
$i \in S_{\underline{i}}=\{0,1, \ldots, n i-1\}=$ node index
$\underline{x} .=\left(\underline{x}_{i}\right)_{i \in S_{\underline{i}}}=$ the nodes of the learned bnet.
$k \in S_{k^{i}}=\left\{0,1, \ldots, n k^{i}-1\right\}=$ states of node $\underline{x}_{i}$
$\mu \in S_{\underline{\mu}^{i}}=\left\{0,1, \ldots, n \mu^{i}-1\right\}=$ states of parents of node $\underline{x}_{i}$.
In the previous section, we assumed a single node ( $n i=1$ ) with no parents $\left(n \mu^{0}=1\right)$ so that we could drop the $i, \mu$ indices. In this section, we eliminate that restriction.

It is convenient to define the magnitude of a bnet $B$ to equal the sum over nodes of the number of free parameters in each TPM:

$$
\begin{equation*}
|B|=\sum_{i}\left(n k^{i}-1\right) n \mu^{i} \tag{47.44}
\end{equation*}
$$

Suppose that we are given nsam samples $\underline{\vec{x}}_{i}=\left(\underline{x}_{i}[\sigma]\right)_{\sigma=0,1, \ldots, n s a m-1}$ of our learned bnet. The count numbers $N_{k, \mu}^{i}$ are defined in terms of those samples as follows:

$$
\begin{equation*}
N_{k, \mu}^{i}=\sum_{\sigma} \mathbb{1}\left(\underline{x}_{i}[\sigma]=k, p a\left(\underline{x}_{i}[\sigma]\right)=\mu\right) . \tag{47.45}
\end{equation*}
$$

It is also convenient to defined count number ratios

$$
\begin{equation*}
N_{k \mid \mu}^{i}=\frac{N_{k, \mu}^{i}}{N_{+, \mu}^{i}} \tag{47.46}
\end{equation*}
$$

Note that $N_{k, \mu}^{i}$ is a positive integer whereas $N_{k \mid \mu}^{i} \in[0,1]$.
Let's denote the components of the TPMs by $\pi_{k \mid \mu}^{i}$ :

$$
\begin{equation*}
\pi_{k \mid \mu}^{i}=P\left(\underline{x}_{i}=k \mid p a\left(\underline{x}_{i}\right)=\mu\right) \approx N_{k \mid \mu}^{i} . \tag{47.47}
\end{equation*}
$$

The rest of this section lists equations that we obtained from the previous section, by adding the new indices $i, \mu$ :

$$
\begin{gather*}
\mathcal{K}\left(N_{\cdot, \mu}^{i}, \alpha_{\cdot, \mu}^{i}\right)=\frac{B\left(N_{\cdot, \mu}^{i}+\alpha_{\cdot, \mu}^{i}\right)}{C I\left(N_{\cdot, \mu}^{i}\right) B\left(\alpha_{\cdot, \mu}^{i}\right)}  \tag{47.48}\\
\hat{\pi}_{k \mid \mu}^{i}=\frac{N_{k, \mu}^{i}+\alpha_{k, \mu}^{i}}{N_{+, \mu}^{i}+\alpha_{+, \mu}^{i}}  \tag{47.49}\\
P\left(N_{\cdot, \mu}^{i} \mid \alpha_{\cdot, \mu}^{i}\right)=\mathcal{K}\left(N_{\cdot, \mu}^{i}, \alpha_{\cdot, \mu}^{i}\right)  \tag{47.50}\\
P\left(N_{\cdot, \mu}^{i} \mid \pi_{\cdot \mid \mu}^{i}, \alpha_{\cdot, \mu}^{i}\right) \approx \operatorname{Mul}\left(N_{\cdot, \mu}^{i}+\alpha_{\cdot, \mu}^{i} ; \pi_{\cdot \mid \mu}^{i}, N_{+, \mu}^{i}+\alpha_{+, \mu}^{i}\right) \tag{47.51}
\end{gather*}
$$

## Claim 28

$$
\begin{align*}
\ln P\left(N_{\cdot, \mu}^{i} \mid \hat{\pi}_{\cdot \mid \mu}^{i}, \alpha_{\cdot, \mu}^{i}\right) & =\sum_{k}\left(N_{k, \mu}^{i}+\alpha_{k, \mu}^{i}\right) \ln \left(\frac{N_{k, \mu}^{i}+\alpha_{k, \mu}^{i}}{N_{+, \mu}^{i}+\alpha_{+, \mu}^{i}}\right)+\ln C\left(N_{\cdot, \mu}^{i}+\alpha_{\cdot, \mu}^{i}\right)  \tag{47.52}\\
& >\sum_{k}\left(N_{k, \mu}^{i}+\alpha_{k, \mu}^{i}\right) \ln \left(\frac{N_{k, \mu}^{i}+\alpha_{k, \mu}^{i}}{N_{+, \mu}^{i}+\alpha_{+, \mu}^{i}}\right)-\frac{1}{2}\left(n k^{i}-1\right) \ln N_{+, \mu}^{i} \tag{47.53}
\end{align*}
$$

### 47.4 Bayesian Scores

- Bayesian Information Criterion (BIC)

$$
\begin{align*}
\text { BIC-score } & =-\sum_{i} \sum_{k, \mu} N_{k, \mu}^{i} \ln \left(\frac{N_{k, \mu}^{i}}{N_{+, \mu}^{i}}\right)+\underbrace{\left[-\frac{|B|}{2} \ln N_{+,+}^{+}\right]}_{\sum_{i} \sum_{\mu} \ln C\left(N_{\cdot, \mu}^{i}\right) \text { would be more accurate }}  \tag{47.54}\\
& \approx \sum_{i} \sum_{\mu} \ln P\left(N_{\cdot, \mu}^{i} \mid \hat{\pi}_{\cdot \mid \mu}^{i}, \alpha_{\cdot, \mu}^{i}=0\right)
\end{align*}
$$

- Bayesian Dirichlet (BD)

$$
\begin{align*}
\text { BD-score } & =\sum_{i} \sum_{\mu} \ln \frac{B\left(N_{\cdot, \mu}^{i}+\alpha_{\cdot, \mu}^{i}\right)}{B\left(N_{\cdot, \mu}^{i}\right)}  \tag{47.56}\\
& =\sum_{i} \sum_{\mu} \ln \left[C I\left(N_{\cdot, \mu}^{i}\right) P\left(N_{\cdot, \mu}^{i} \mid \alpha_{\cdot, \mu}^{i}\right)\right] \tag{47.57}
\end{align*}
$$

- BD equivalent ( BDe )

$$
\begin{equation*}
\text { BDe-score }=\operatorname{BD} \text {-score }\left(\alpha_{k, \mu}^{i}=\alpha^{\prime} N_{k, \mu}^{i}\right) \tag{47.58}
\end{equation*}
$$

where $\alpha^{\prime}$ is a free parameter.

- BD equivalent unified (BDeu)

$$
\begin{equation*}
\mathrm{BDeu} \text {-score }=\mathrm{BD} \text {-score }\left(\alpha_{k, \mu}^{i}=\frac{\alpha^{\prime}}{n k^{i} n \mu^{i}}\right), \tag{47.59}
\end{equation*}
$$

where $\alpha^{\prime}$ is a free parameter. The BDeu score satisfies score equivalence; i.e., it is the same for all DAGs in an equivalence class of observational equivalent DAGs. See Chapter 38 for more information about observational equivalence.

### 47.5 Information Theoretic scores

- Maximum likelihood

$$
\begin{align*}
\text { ML-score } & =\sum_{i} \sum_{k, \mu} N_{k, \mu}^{i} \ln N_{k \mid \mu}^{i}  \tag{47.60}\\
& =-\sum_{i} H\left(\underline{k}^{i} \mid \underline{\mu}^{i}\right) \tag{47.61}
\end{align*}
$$

where $P_{\underline{k}^{i} \mid \underline{\mu}^{i}}(k \mid \mu)=N_{k \mid \mu}^{i}$ and $P_{\underline{k}^{i}, \underline{\mu}^{i}}(k, \mu)=N_{k, \mu}^{i}$.

- Bayesian Information Criterion (BIC), aka Minimum Description Length (MDL)

$$
\begin{align*}
\text { BIC-score } & =\text { ML-score }-\frac{|B|}{2} \ln N_{+,+}^{+}  \tag{47.62}\\
& \approx \sum_{i} \sum_{k, \mu} N_{k, \mu}^{i} \ln \frac{N_{k \mid \mu}^{i}}{\sqrt{N_{+,+}^{+}}} \tag{47.63}
\end{align*}
$$

- Akaike Information Criterion (AIC)

$$
\begin{align*}
\text { AIC-score } & =\text { ML-score }-|B|  \tag{47.64}\\
& \approx \sum_{i} \sum_{k, \mu} N_{k, \mu}^{i}\left[\ln N_{k \mid \mu}^{i}-1\right] \tag{47.65}
\end{align*}
$$

## Chapter 48

## Simpson's Paradox

This chapter is based on Chapter 6 of "The Book of Why", Ref. [30]. See also Ref. 80 ] and references therein.

Simpson's paradox is a recurring nightmare for all statisticians overseeing a clinical trial for a medicine. It is possible that if they leave out a certain "confounding" variable from a study, the study's conclusion on whether a medicine is effective or not, might be, without measuring that confounding variable, the opposite of what it would have been had that variable been measured.

Simpson's Paradox is greatly clarified by Judea Pearl's theory of causality. At the end of this chapter, we explain how.

Here is a simple example of Simpson's Paradox.
An equal number of patients of male and female genders are given a heart medicine or a placebo in a double blind study. Some subsequently have a heart attack. Let
$\underline{a}=$ heart attack? No=0, Yes=1
$\underline{t}=$ took medicine? $\mathrm{No}=0$, Yes $=1$
$\underline{g}=$ gender? Female $=0$, Male $=1$

Figure 48.1: bnet for a simple example of Simpson's paradox. Here node $\underline{g}$ is a chain junction and a mediator.

This situation can be modeled by either bnet Fig.48.1. or bnet Fig.48.2. The two bnets are probabilistically equivalent (i.e., they both represent the same proba-

Figure 48.2: bnet that is probabilistically but not physically equivalent to bnet Fig 48.1. Here node $\underline{g}$ is a fork junction and a confounder.
bility distribution $P(a, t, g))$ because

$$
\begin{equation*}
P(g \mid t) P(t)=P(g, t)=P(t \mid g) P(g) . \tag{48.1}
\end{equation*}
$$

For the bnet Fig.48.1, one has

$$
\begin{equation*}
P(a, g, t)=P(a \mid g, t) P(g \mid t) P(t) . \tag{48.2}
\end{equation*}
$$

Therefore,

$$
\begin{equation*}
P(a=1 \mid t)=\sum_{g} P(a=1 \mid t, g) P(g \mid t)=E_{\underline{g} \mid t} P(a=1 \mid t, \underline{g}), \tag{48.3}
\end{equation*}
$$

where $E_{g \mid t}$ is a conditional expected value (a kind of weighted average).
Suppose $q_{0}, q_{1}$ are non-negative real numbers. For the vector $\vec{q}=\left(q_{0}, q_{1}\right)$ :
Define a negative outcome (or failure or $q_{t}$ increasing with $t$ ) if $q_{0} \leq q_{1}$.
Define a positive outcome (or success or $q_{t}$ decreasing with $t$ ) if $q_{0} \geq q_{1}$.
Let

$$
\begin{equation*}
\vec{q}^{g}=[P(\underline{a}=1 \mid t, g)]_{t=0,1} \tag{48.4}
\end{equation*}
$$

for $g=0,1$, and

$$
\begin{equation*}
\vec{q}^{*}=[P(\underline{a}=1 \mid t)]_{t=0,1} . \tag{48.5}
\end{equation*}
$$

It is possible (see Fig. 48.3 for a graphical explanation of how) to find perverse cases in which $P(a=1 \mid t, g=0)$ and $P(a=1 \mid t, g=1)$ increase with $t$ but $P(a=1 \mid t)$ decreases with $t$. So it is possible to conclude that the medicine is a failure for each of the two $g$ populations considered separately, yet the medicine is a success when both populations are "amalgamated". The lesson is that a "trend reversal" is possible upon amalgamation. Trends are not necessarily preserved when we do a weighted average of type $E_{\underline{g} \mid t}$. $E_{\underline{g} \mid t}$ is an expected value on the random variable $\underline{g}$ conditioned on the root random variable $t$.

So far, we have proven that probabilistically, the drug can be a failure for the populations of both sexes considered separately, but a success for the aggregate population.

Figure 48.3: $\vec{q}^{0}, \vec{q}^{1}$ vectors and bounding box for vector $\vec{q}^{*}$.

### 48.1 Pearl Causality

Pearl Causality would add the following two important insights to this problem:

1. bnets Fig 48.1 and Fig. 48.2 , although they are probabilistically equivalent, do not represent the same physical situation. In fact, only Fig. 48.2 occurs in this case.
2. To decide whether the medicine is effective, we must apply a do() operator to the $\underline{t}$ variable in Fig 48.2 . The effect of that $d o()$ operator is to erase the arrow going from $\underline{g}$ to $\underline{t}$. This in turn means that the average $E_{\underline{g} \mid t}$ in our equation for $P(a=1 \mid t)$ becomes a simpler average $E_{g}$ which is independent of $\underline{t}$. But for such an average, the bounding box in Fig 48.3 degenerates to its diagonal line that connects the tips of the two vectors $\vec{q}^{0}$ and $\vec{q}^{1}$. The vector $\vec{q}^{*}$ must now fall on that diagonal line and must therefore also fall in the success region.

In conclusion, as Judea Pearl would say, if we ask the right question to Nature, i.e., what is $P[a=1 \mid d o(\underline{t}=t)]$ for $t=0,1$, we get as an answer that the aggregate population preserves rather than reverses the unanimous trend of the two gendered populations.

### 48.2 Numerical Example

| $(a, t, g)$ | number of patients <br> segregated by gender | number of patients <br> of either gender |
| :--- | :--- | :--- |
| $0,0,0$ | 19 | 47 |
| $0,0,1$ | 28 | 49 |
| $0,1,0$ | 37 |  |
| $0,1,1$ | 12 |  |
| $1,0,0$ | 1 | 11 |
| $1,0,1$ | 12 |  |
| $1,1,0$ | 3 |  |
| $1,1,1$ | 8 |  |

Table 48.1: Data for numerical example of Simpson's Paradox. This fictitious data was taken directly from Table 6.4, page 210 of "The Book of Why", Ref. 30].

$$
\begin{align*}
& P(a \mid t, g)=\begin{array}{c|cccc} 
& 0,0 & 0,1 & 1,0 & 1,1 \\
\hline 0 & 19 / 20 & 28 / 40 & 37 / 40 & 12 / 20 \\
1 & 1 / 20 & 12 / 40 & 3 / 40 & 8 / 20
\end{array}  \tag{48.6}\\
& P(a \mid t)=\begin{array}{c|cc} 
& 0 & 1 \\
\hline 0 & 47 / 60 & 49 / 60 \\
1 & 13 / 60 & 11 / 60
\end{array}  \tag{48.7}\\
& \begin{array}{l}
P(a=1, t=1, g=0) \\
\sum_{\sum_{a} P(a, t=1, g=0)}^{P}=P(a=1 \mid t=1, g=0)=\frac{3}{40} \\
\sum_{\sum_{a} P(a=1, t=0, g=0)}^{\sum_{a} P(a, t=0, g=0)}=P(a=1 \mid t=0, g=0)=\frac{1}{20}=\frac{2}{40}
\end{array}  \tag{48.8}\\
& \begin{array}{l}
\frac{P(a=1, t=1, g=1)}{\sum_{a} P(a, t=1, g=1)}=P(a=1 \mid t=1, g=1)=\frac{8}{20}=\frac{16}{40} \\
\sum_{a(a=1, t=0, g=1)}^{\sum_{a} P(a, t=0, g=1)}=P(a=1 \mid t=0, g=1)=\frac{12}{40}
\end{array}  \tag{48.9}\\
& \frac{\sum_{g} P(a=1, t=1, g)}{\sum_{g} \sum_{a} P(a, t=1, g)}=P(a=1 \mid t=1)=\frac{11}{60} \\
& \frac{\sum_{g} P(a=1, t=0, g)}{\sum_{g} \sum_{a} P(a, t=0, g)}=P(a=1 \mid t=0)=\frac{13}{60} \tag{48.10}
\end{align*}
$$

Note that the right hand side of Eq. 48.8 is higher for $t=1$ than for $t=0$. Same trend occurs in Eqs 48.9 but is reversed in Eqs 48.10.

## Chapter 49

## Structure and Parameter Learning for Bnets

Learning a bnet from data is a computationally intensive NP-complete problem. Therefore, the best one can hope for is for heuristic algorithms that solve this problem approximately. A huge number of such algorithms have been tried and continue to be tried. Luckily, there exists a free open source software library called bnlearn that covers many of them. The goal of this chapter is to give a brief overview of the subject of bnet learning, after which we recommend to those readers who want to pursue this subject further, to learn bnlearn.

This chapter is based on the bnlearn website Ref.[33], and on a 2019 survey paper [34] by Scutari et al. I highly recommend looking at both. Refs. [2] and [15] were also helpful to me in understanding this subject.
bnlearn (Ref.[33]) (free, open source) is very comprehensive and well maintained. It is written mostly in C with an R frontend. It was developed by Marco Scutari and collaborators over a time period of more than 10 years, and is still under active development. How things stand in the field of bnet learning software reminds me of how things stand in the field of linear algebra (LA) software. Perfecting and optimizing LA software takes many years so I would not advise you to write your own LA software library starting from scratch. There is no need to do so. Instead, you can use LAPACK (free, open source), which has been perfected and expanded for decades by world experts. I view bnlearn as the LAPACK of bnet learning.

### 49.1 Overview

To give the reader an overview of the subject and of bnlearn itself, here is a highly simplified tree, compiled from the bnlearn website and documentation, of some of the subjects covered by bnlearn.
Parameter Learning
$\downarrow$ missing data
Structure Learning

```
    tree-like structures given a priori
    Naive Bayes
    Chow-Liu tree
    Tree Augmented Naive Bayes (TAN)
    ARACNE

        parameter estimation (maximum likelihood and Bayesian)
        inference, conditional probability queries
        cross-validation
```

Let

- $\mathrm{PL}=$ parameters learning (i.e, learning the TPMs)
- $\mathrm{SL}=$ structure learning (i.e., learning the DAG )

PL is easy, once the structure is known. PL assuming no missing data goes as follows. Using the notation of Chapter 47, define

$$
\begin{equation*}
\pi_{k \mid \mu}^{i}=P\left(\underline{x}_{i}=k \mid p a\left(\underline{x}_{i}\right)=\mu\right) . \tag{49.1}
\end{equation*}
$$

Then $\pi_{k \mid \mu}^{i}$ can be estimated from the data $N_{k, \mu}^{i}$ using:

$$
\begin{equation*}
\pi_{k \mid \mu}^{i} \approx N_{k \mid \mu}^{i}=\frac{N_{k, \mu}^{i}}{N_{+, \mu}^{i}} \tag{49.2}
\end{equation*}
$$

PL described by Eq. 49.2 is only for discrete nodes with no missing data. bnlearn can also do PL with missing data and continuous (Gaussian linear only) nodes. See Chapter 32 on missing data and Chapter 19 on Gaussian linear nodes. SL actually does PL and SL at the same time.

There are 3 main types of SL: score based, constraint based, and hybrid. bnlearn can perform many algorithms of each of these 3 types of SL. It can perform most of them with either all-discrete, or all-continuous or mixed nodes. It can perform many of them in parallel mode. The 2019 survey paper Ref. [34] by Scutari et al compares the performance of many different bnet learning algorithms.

### 49.2 Score based SL algorithms

Score based SL algorithms require scoring bnets (with either all-discrete, all-continuous or mixed nodes). See Chapter 47 for an introduction to scoring bnets. The BIC score explained in that chapter is very popular and works for all-discrete, all-continuous or mixed nodes.

Score-based SL algorithms apply standard optimisation techniques. In the Hill Climbing algorithm, the current best bnet is changed slightly and then given a score that measures how well it fits the data. The bnet with the highest (=best) score so far, as well as that highest score, are stored. (Hence, this is called a greedy search). The process continues until the latest highest score stops changing. The problem with being greedy all the time is that the answer might converge to a local maximum. To mitigate this problem and allow some probability of visiting more than one local maximum, one uses a Tabu Table, random restarts, simulated annealing, genetic algorithms, etc.

### 49.3 Constraint based SL algorithms

To fully understand constraint based SL algorithms, the reader is advised to read Chapters 14 and 38 first.

Constraint based SL algorithms require estimating from the data the conditional independence $\underline{x} . \perp_{P} \underline{y} . \mid \underline{a}$. for any 3 disjoint multinodes $\underline{x} ., \underline{y} ., \underline{a}$.. This can be done by estimating the conditional mutual information (CMI) $H(\underline{x} .: \underline{y} . \mid \underline{a}$.$) .$ bnlearn can calculate CMI and other metrics of $\underline{x} . \perp_{P} \underline{y} . \mid \underline{a}$. . All these metrics are very similar; they all measure how close $P(x . \mid y ., a$.$) and \bar{P}(x . \mid a$.$) are.$

The first constraint-based SL algorithm was the Inductive Causation (IC) algorithm proposed by Pearl and Verma in 1991. Incremental improvements have been proposed since then, such as the PC family of algorithms, Grow-Shrink and the Incremental Association Markov Blanket (IAMB) family of algorithms.

### 49.4 Pseudo-code for some bnet learning algorithms

```
Algorithm 2: Pseudo-code for Hill Climbing algorithm
    Input : Data \(D\), Vertices \(V\)
    Output: a bnet \(B=(G, T)\), where \(G=(V, E)\) is a DAG, where \(V\) are its
                vertices (nodes) and \(E\) are its edges (arrows). \(T\) are all its
                Transition Probability Matrices (TPMs) \(T=T P M s(G, D)\).
    \(E \leftarrow \emptyset\)
    \(T \leftarrow \emptyset\)
    \(B \leftarrow(V, E, T)\)
    maxscore \(\leftarrow-\infty\)
    // \(D E=\) all possible directed edges
    \(D E=\{\underline{x} \rightarrow \underline{y} \in V \times V: \underline{x} \neq \underline{y}\}\)
    again \(\leftarrow\) True
    while again do
        for all \(\underline{x} \rightarrow \underline{y} \in D E\) do
            // add arrow
            \(E_{+} \leftarrow E \cup\{\underline{x} \rightarrow \underline{y}\}\)
            // delete arrow
            \(E_{-} \leftarrow E-\{\underline{x} \rightarrow \underline{y}\}\)
            // reverse arrow
            \(E_{R} \leftarrow E_{-} \cup\{\underline{y} \rightarrow \underline{x}\}\)
            for \(E^{\prime}=E_{+}, E_{-}, E_{R}\) do
                if \(E^{\prime} \neq E\) and \(G^{\prime}=\left(V, E^{\prime}\right)\) is a legal \(D A G\) then
                \(T^{\prime} \leftarrow T P M s\left(G^{\prime}, D\right)\)
                \(B^{\prime} \leftarrow\left(G^{\prime}, T^{\prime}\right)\)
                newscore \(=\) BIC-score \(\left(B^{\prime}\right)\)
                if newscore \(>\) maxscore then
                \(B \leftarrow B^{\prime}\)
                maxscore \(\leftarrow\) newscore
                    else
                        again \(\leftarrow\) False
    return \(B\)
```

```
Algorithm 3: Pseudo-code for PC-Stable algorithm
    Input : Data \(D\), Vertices (nodes) \(V\), tolerance in CMI \(\epsilon>0\)
    Output: partially oriented acyclic graph \(G=(V, E, U E)\), where \(V\) are the
                vertices (nodes), \(E\) are the oriented edges (arrows) and \(U E\) are the
                unoriented edges.
    \(E \leftarrow \emptyset\)
    // initialize \(U E\) to fully-connected undirected graph
    \(U E \leftarrow\{\underline{x}-\underline{y} \in V \times V: \underline{x}-\underline{y}=\underline{y}-\underline{x}, \underline{x} \neq \underline{y}\}\)
    // Shrink phase. Deletes edges from \(E\).
    for \(\lambda=0,1,2, \ldots,|V|-2\) do
        for all \(\underline{x}-\underline{y} \in U E\) do
        for all \(\bar{S}=\{\underline{a} \in V: \underline{x}-\underline{a} \in U E, \underline{a} \neq \underline{x}, \underline{y}\} \ni|S|=\lambda\) do
                        if \(H(\underline{x}: \underline{y} \mid S)<\epsilon\) then
                /* If there were an arrow between \(\underline{x}\) and \(\underline{y}\), then
                conditioning on \(S\) would not be enough to interrupt
                info transmission \(H(\underline{x}: \underline{y} \mid S)\) between \(\underline{x}\) and \(y \quad\) */
                \(U E \leftarrow U E-\{\underline{x}-\underline{y}\}\)
                \(S(\underline{x}-\underline{y}) \leftarrow S\)
    // Growth phase. Adds v structures to \(E\).
    for all \(\underline{x}, \underline{y}, \underline{a}\) such that \(\underline{x}-\underline{a} \in U E, \underline{a}-\underline{y} \in U E, \underline{x}-\underline{y} \notin U E, \underline{a} \notin S(\underline{x}-\underline{y})\) do
        /* If there were no collider at \(\underline{a}\), then there would be info
            transmission between \(\underline{x}\) and \(\underline{y} \quad * /\)
        \(U E \leftarrow U E-\{\underline{x}-\underline{a}, \underline{a}-\underline{y}\}\)
        \(E \leftarrow E \cup\{\underline{x} \rightarrow \underline{a}, \underline{y} \rightarrow \underline{a}\}\)
    // Orienting edges.
    again \(\leftarrow\) True
    size \(\leftarrow|U E|\)
    while again do
        for all \(\underline{x}-\underline{y} \in U E\) do
        if \(\underline{x} \rightarrow \underline{y} \in E, \underline{y}-\underline{z} \in U E, \underline{x}-\underline{z} \notin U E\), \(\nexists \underline{w} \ni \underline{w} \rightarrow \underline{y} \in E\) then
            // to avoid introducing new v structure
            \(U E \leftarrow U E-\{\underline{y}-\underline{z}\}\)
            \(E \leftarrow E \cup\{\underline{y} \rightarrow \underline{z}\}\)
        if \(\underline{x} \rightarrow \underline{y} \in E\) and there is directed path from \(\underline{x}\) to \(\underline{y}\) in \(E\) then
            // to avoid introducing cycles
            \(U E \leftarrow U E-\{\underline{x}-\underline{y}\}\)
            \(E \leftarrow E \cup\{\underline{x} \rightarrow \underline{y}\}\)
        newsize \(\leftarrow|U E|\)
        if size \(==\) newsize then
            again \(\leftarrow\) False
        else
            size \(\leftarrow\) newsize
return \(G=(V, E, U E)\)
```

## Chapter 50

## Synthetic Controls

This chapter is based on Refs. 5] and [3].
This chapter assumes that the reader has read Chapter 11 on the Difference-in-Differences (DID) method.

The Synthetic Controls (SC) method is a simple enhancement of the DID method. SC enhances DID in two simple yet powerful ways:

1. Better time resolution. DID considers just 2 time-snapshots (i.e., a timeseries with only 2 times) whereas SC considers arbitrarily many time-snapshots (i.e., a time-series with more than 2 times).
2. Weighted average of controls. DID divides the population of individuals into just 2 kinds: the treated and the untreated (aka controls). SC divides the total population into treated and controls just like DID does, but it goes further and divides the control population into multiple subpopulations, and calculates a weighted average, called a "synthetic control", of those subpopulations. The weights of the synthetic control are chosen so that it mimics as closely as possible the behavior of the treated population for all times measured before the treatment was applied.

Let us describe these two enhancements more precisely.

- timing: Let $t_{k}$ for $k=0,1, \ldots, n p r e-1$ be the pre-treatment times at which a measurement occurs. Let $t_{k}$ for $k=$ npre, npre $+1, \ldots$, ntimes -1 be the post-treatment times at which a measurement occurs. Note that npre + npost $=$ ntimes. Note that $t_{*}=t_{n p r e+1}$ is the first measurement time after the treatment is applied, $t_{0}$ is the first measurement time, and $t_{\text {fin }}=t_{\text {ntimes }-1}$ is the last one.
- subpopulations: Let $S_{1}=\left\{\sigma_{1}\right\}$ be the set of treated units (just one). Let $S_{0}=\left\{\sigma: \sigma \neq \sigma_{1}\right\}$ be the set of untreated units (i.e., controls). Let nsam $=$ number of all units $\sigma, n_{1}=\left|S_{1}\right|=1$, and $n_{0}=\left|S_{0}\right|=n s a m-1$.
- weights:

Figure 50.1: Pictorial representation of the Synthetic Controls (SC) method. The outcome $y$ of the synthetic control unit is colored red and that of the treated unit is colored blue. They roughly agree for $t<t_{*}$.

We want to define a time-independent weight $w^{\sigma}$ for each unit $\sigma$ in such a way that the output $y_{t}^{\sigma}$ for the synthetic control unit behaves like the output for the treated unit $\sigma_{1}$ for $t<t_{*}$.

Let

$$
\begin{equation*}
w^{\sigma_{1}}=0 \tag{50.1}
\end{equation*}
$$

and

$$
\begin{equation*}
w^{n_{0}}=\left\{w^{\sigma}\right\}_{\sigma \neq \sigma_{1}} . \tag{50.2}
\end{equation*}
$$

Define a cost function $\mathcal{C}$ :

$$
\begin{equation*}
\mathcal{C}\left(w^{n_{0}}\right)=\sum_{t<t_{*}}\left(y_{t}^{\sigma_{1}}-\sum_{\sigma \neq \sigma_{1}} w^{\sigma} y_{t}^{\sigma}\right)^{2} \tag{50.3}
\end{equation*}
$$

Then calculate $w^{n_{0}}$ by minimizing the cost function, subject to the constraint that $w^{n_{0}}$ be a probability distribution:

$$
\begin{equation*}
w^{n_{0}}=\underset{W^{n_{0}}}{\operatorname{argmin}}\left\{\mathcal{C}\left(W^{n_{0}}\right): W^{\sigma} \geq 0, \sum_{\sigma \neq \sigma_{1}} W^{\sigma}=1\right\} \tag{50.4}
\end{equation*}
$$

Now that we have defined a weight $w^{\sigma}$ for every unit $\sigma$, we can define

$$
y_{t}^{\xi}= \begin{cases}y_{t}^{\sigma_{1}} & \text { if } \xi=1  \tag{50.5}\\ \sum_{\sigma \neq \sigma_{1}} w^{\sigma} y_{t}^{\sigma} & \text { if } \xi=0\end{cases}
$$

and

$$
\begin{equation*}
\delta_{t}=y_{t}^{\xi=1}-y_{t}^{\xi=0} \tag{50.6}
\end{equation*}
$$

$\delta_{t}$ is illustrated in Fig 50.1. It measures the time dependent gap (causal effect) between the outcome (i.e., $y$ ) of the treated unit $\sigma_{1}$ and the outcome of the synthetic control unit.

### 50.1 A bnet $G_{t}$ with weighted treatment outcomes

Our next goal is to analyze the SC method using the formalism of PO theory. To attain that goal, we will first define in this section a bnet $G_{t}$. The bnet $G_{t}$ in this chapter differs in two important respects from the bnet $G_{t}$ defined in Chapter 11 on the DID method. First, the $G_{t}$ in the DID chapter is defined for only 2 measurement times whereas the $G_{t}$ in this chapter is defined for more than 2 measurement times. Second, the $G_{t}$ in this chapter defines $\underline{y}_{t}$ for $d=0$ as a weighted average over control subpopulations.

$G_{t, \text { unit }}$

$G_{t}$

Figure 50.2: $t \in\left\{t_{0}, t_{1}, \ldots, t_{f i n}\right\}$. The bnet $G_{t}$ is defined by counting units $\sigma$ for the bnet $G_{t, u n i t}$.

Suppose $t \in\left\{t_{0}, t_{1}, \ldots, t_{\text {fin }}\right\}$. For $\xi \in\{0,1\}$, define the following unit counts:

$$
\begin{equation*}
N_{d, y_{t}, x}^{\xi}=\sum_{\sigma \in S_{\xi}} \mathbb{1}\left(d=d^{\sigma}, y_{t}=y_{t}^{\xi}, x=x^{\sigma}\right) . \tag{50.7}
\end{equation*}
$$

Define also

$$
\begin{equation*}
N_{d, y_{t}, x}=\sum_{\xi \in\{0,1\}} \mathbb{1}(\xi, d) N_{d, y_{t}, x}^{\xi} . \tag{50.8}
\end{equation*}
$$

Henceforth, sums over the subscripts of $N_{d, y_{t}, x}$ will be indicated by a dot. For example, $N_{\cdot, y_{t}, x}=\sum_{d} N_{d, y_{t}, x}$.

The TPMs, printed in blue, for the bnet $G_{t}$ shown in Fig.50.2, are as follows.

$$
\begin{gather*}
P_{\underline{x}}(x)=\frac{N_{\cdot,, x}}{N_{\cdot, \cdot,}}  \tag{50.9}\\
P_{\underline{d} \mid \underline{x}}(d \mid x)=\frac{N_{d, \cdot x}}{N_{\cdot,,, x}} \tag{50.10}
\end{gather*}
$$

$$
\begin{equation*}
P_{\underline{y}_{t} \mid \underline{d}, \underline{x}}\left(y_{t} \mid d, x\right)=\frac{N_{d, y_{t}, x}}{N_{d,, x}} \tag{50.11}
\end{equation*}
$$

### 50.2 PO analysis

In this section, we show how to analyze the SC method using the formalism of PO theory.

$$
G_{t} \quad G_{t, i m}
$$

Figure 50.3: $t \in\left\{t_{0}, t_{1}, \ldots, t_{\text {fin }}\right\}$. Bnet $G_{t, i m}=\kappa_{\underline{d} \rightarrow \underline{y}_{t}}(\tilde{d}) G_{t}$ is obtained by applying the imagine operator to arrow $\underline{d} \rightarrow \underline{y}_{t}$ of bnet $G_{t}$.

As usual for PO theory, we will consider expected values of $y_{t}^{\sigma}$ :

$$
\begin{equation*}
E_{\sigma \mid \tilde{d}, x}\left[y_{t}^{\sigma}(d)\right]=E_{y_{t} \mid \tilde{d}, x}\left[\underline{y}_{t}(d)\right]=\mathcal{Y}_{d \mid \tilde{d}, x}(t) \tag{50.12}
\end{equation*}
$$

To calculate these expected values, we need a "model" with probability distributions. In this case, the needed model and probability distributions are provided by the bnets depicted in Fig 50.3. The TPMs, printed in blue, for the bnet $G_{t, i m}$ in Fig 50.3 , are as follows. Note that the TPMs for the bnet $G_{t, i m}$ are defined in terms of the TPMs for the bnet $G_{t}$.

$$
\begin{gather*}
P(x)=P_{\underline{x}}(x)  \tag{50.13}\\
P(d \mid x)=P_{\underline{d} \mid \underline{x}}(d \mid x)  \tag{50.14}\\
P\left(y_{t} \mid \tilde{d}, x\right)=P_{\underline{y}_{t} \mid \underline{d}, \underline{x}}\left(y_{t} \mid \tilde{d}, x\right)  \tag{50.15}\\
P\left((\tilde{d})^{\prime}\right)=\delta\left((\tilde{d})^{\prime}, \tilde{d}\right) \tag{50.16}
\end{gather*}
$$

Figure 50.4: Four different time-dependent expected values $\mathcal{Y}_{d \mid \tilde{d}}(t)$ of $y_{t}^{\sigma}$ for bnet $G_{t, i m}$ The $2 *$ ntimes magenta stars represents the $2 *$ ntimes SC measurements.

Henceforth, for simplicity, we will omit the confounder state $x$ from the indices of $\mathcal{Y}$; i.e., we will write $\mathcal{Y}_{d \mid \tilde{d}}(t)$ instead of $\mathcal{Y}_{d \mid \tilde{d}, x}(t)$. The fact that we will not explicitly mention $x$ does not mean that it doesn't exist or that it doesn't affect our analysis. If there are confounders, they cannot be neglected. As discussed in Chapter 39 under the subject of strata-matching in PO , one must condition $\mathcal{Y}$ on a single $x$ stratum and, later on, one must average over all the possible $x$ strata.

Let $\mathcal{M} \mathcal{Y}_{d \mid \tilde{d}}(t)$ denote the measured $\mathcal{Y}_{d \mid \tilde{d}}(t)$. We define this quantity as

$$
\begin{equation*}
\mathcal{M} \mathcal{Y}_{d \mid \tilde{d}}(t)=\mathcal{Y}_{d \mid \tilde{d}}(t)\left[\mathbb{1}\left(d=0, t<t_{*}\right)+\mathbb{1}\left(d=\tilde{d}, t \geq t_{*}\right)\right] \tag{50.17}
\end{equation*}
$$

Now we claim that the $\mathrm{SC} \delta_{t}$ calculated in the previous section can be expressed in PO formalism as follows:

$$
\begin{equation*}
\delta_{t}=\mathcal{Y}_{1 \mid 1}(t)-\mathcal{Y}_{0 \mid 0}(t)=S D O_{t} \tag{50.18}
\end{equation*}
$$

for $t \geq t_{*}$. Fig. 50.4 depicts the four functions $\mathcal{Y}_{d \mid \tilde{d}}(t)$ for $t$ in the interval $\left[t_{0}, t_{f i n}\right]$ and for $d, \tilde{d} \in\{0,1\}$. The $\mathcal{Y}$ coordinates of the $2 *$ ntimes magenta stars in Fig 50.4 can be calculated using bnet $G_{t}$. Note that in Fig. 50.4 , we display a large gap between the curves $\mathcal{Y}_{0 \mid \tilde{d}}(t)$ for $\tilde{d} \in\{0,1\}$. In reality, $P\left(y_{t} \mid \tilde{d}, x\right)$ has been constructed so as to make that gap as small as possible. Thus, to a good(?) approximation,

$$
\begin{equation*}
\delta_{t} \approx A T T_{t} \tag{50.19}
\end{equation*}
$$

Hence, unlike in the DID method, in the SC method, to a good(?) approximation, we don't have to worry about parallel trends.

## Chapter 51

## Transportability: COMING SOON

Ref. [28]

$$
P^{*}(y \mid \rho \underline{x}=x)=\sum_{z} P(y \mid \rho \underline{x}=x) P^{*}(z)
$$

$$
P^{*}(y \mid \rho \underline{x}=x)=P(y \mid \rho \underline{x}=x)
$$

$$
P^{*}(y \mid \rho \underline{x}=x)=\sum_{z} P(y \mid \rho \underline{x}=x, z) P^{*}(z \mid x)
$$

## Chapter 52

## Turbo Codes

This chapter is based on Ref.[17].
In this chapter, vectors with $n$ components will be indicated by an $n$ superscript. For example, $a^{n}=\left(a_{0}, a_{1}, \ldots, a_{n-1}\right)$.

Consider an n-letter message $u^{n}=\left(u_{0}, u_{1}, \ldots, u_{n-1}\right)$, where for all $i, u_{i} \in \mathcal{A}$ is an element of an alphabet $\mathcal{A}$, and where for all $i$, the $\underline{u}_{i}$ are i.i.d.. Suppose $u^{n}$ is encoded deterministically in two different ways, $e_{1}\left(u^{n}\right)$ and $e_{2}\left(u^{n}\right)$. After passing through the same memoryless channel, the variables $u^{n}, e_{1}, e_{2}$ become $\tilde{u}^{n}, \tilde{e}_{1}, \tilde{e}_{2}$, respectively. The letter $u$ stands for unencoded, and $e$ for encoded. Quantities with a tilde $\tilde{u}^{n}, \tilde{e}_{1}, \tilde{e}_{2}$ occur after channel passage and are visible (measurable). Quantities without a tilde $u^{n}, e_{1}, e_{2}$ are hidden (unmeasurable).

The situation just described can be represented by the bnet Fig 52.1, or by its abridged version Fig 52.2. But note that the abridged version does not show explicitly that the $u_{i}$ are i.i.d. or that the channel is memoryless (i.e., that the $u_{i}$ for all $i$ pass independently through the channel).

Define

$$
\begin{equation*}
x=\left(u^{n}, e_{1}, e_{2}\right) \tag{52.1}
\end{equation*}
$$

and

$$
\begin{equation*}
\tilde{x}=\left(\tilde{u}^{n}, \tilde{e}_{1}, \tilde{e}_{2}\right) . \tag{52.2}
\end{equation*}
$$

Fig 52.1 implies that

$$
\begin{equation*}
P(x, \tilde{x})=P\left(\tilde{u}^{n} \mid u^{n}\right)\left[\prod_{r=1,2} P\left(\tilde{e}_{r} \mid e_{r}\right) P\left(e_{r} \mid u^{n}\right)\right] P\left(u^{n}\right) . \tag{52.3}
\end{equation*}
$$

Because the $u^{n}$ are i.i.d.,

$$
\begin{equation*}
P\left(u^{n}\right)=\prod_{i} P\left(u_{i}\right) . \tag{52.4}
\end{equation*}
$$

Figure 52.1: Turbo coding B net representing a message being encoded two different ways and then the original message and the 2 encodings pass through a memoryless channel.

Figure 52.2: Abridged version of Fig 52.1.
Because the channel is memoryless,

$$
\begin{equation*}
P\left(\tilde{u}^{n} \mid u^{n}\right)=\prod_{i} P\left(\tilde{u}_{i} \mid u_{i}\right) . \tag{52.5}
\end{equation*}
$$

Because the encoding is deterministic, we must have for $r=1,2$

$$
\begin{equation*}
P\left(e_{r} \mid u^{n}\right)=\delta\left(e_{r}, e_{r}\left(u^{n}\right)\right) . \tag{52.6}
\end{equation*}
$$

Define the belief functions

$$
\begin{equation*}
B E L_{i}=B E L_{i}\left(\underline{u}_{i}=a\right)=P\left(\underline{u}_{i}=a \mid \tilde{x}\right) . \tag{52.7}
\end{equation*}
$$

The best estimate of $u_{j}$ given all visible evidence $\tilde{x}$ is

$$
\begin{equation*}
\hat{u}_{i}=\underset{u_{i}}{\operatorname{argmax}} B E L_{i}\left(u_{i}\right) . \tag{52.8}
\end{equation*}
$$

Define the probability functions

$$
\begin{equation*}
\pi_{i}=\pi_{i}\left(u_{i}\right)=P\left(u_{i}\right) \tag{52.9}
\end{equation*}
$$

and the likelihood functions

$$
\begin{equation*}
\lambda_{i}=\lambda_{i}\left(u_{i}\right)=P\left(\tilde{u}_{i} \mid u_{i}\right) . \tag{52.10}
\end{equation*}
$$

For $r=1,2$, define the Kernel functions

$$
\begin{equation*}
K_{r}=K_{r}\left(u^{n}\right)=P\left(\tilde{e}_{r} \mid e_{r}=e_{r}\left(u^{n}\right)\right) . \tag{52.11}
\end{equation*}
$$

In this book, $\mathcal{N}(!a)$ denotes a normalization constant that does not depend on a. Define

$$
\begin{equation*}
\mathcal{N}_{i}=\mathcal{N}\left(!u_{i}\right) . \tag{52.12}
\end{equation*}
$$

## Claim 29

$$
\begin{equation*}
B E L_{i}=\mathcal{N}_{i} \lambda_{i} \pi_{i} \mathcal{T}_{i}^{K_{1} K_{2}}\left[\prod_{j \neq i} \lambda_{j} \pi_{j}\right] \tag{52.13}
\end{equation*}
$$

where $\mathcal{T}_{i}^{K}(\cdot)$ with $K=K_{1} K_{2}$ is an operator (transform) that acts on functions of $u^{n}$ :

$$
\begin{equation*}
\mathcal{T}_{i}^{K}(\cdot)=\sum_{u^{n}} \delta\left(u_{i}, a\right) K\left(u^{n}\right)(\cdot) \tag{52.14}
\end{equation*}
$$

## proof:

$$
\begin{align*}
& P\left(\underline{u}_{i}=a \mid \tilde{x}\right)= \\
& \quad=\sum_{x} \delta\left(u_{i}, a\right) P(x \mid \tilde{x})  \tag{52.15}\\
& \quad=\sum_{x} \delta\left(u_{i}, a\right) \frac{P(\tilde{x} \mid x) P(x)}{P(\tilde{x})}  \tag{52.16}\\
& \quad=\mathcal{N}(!a) \sum_{x} \delta\left(u_{i}, a\right) P(\tilde{x} \mid x) P(x)  \tag{52.17}\\
& \quad=\mathcal{N}(!a) \sum_{x} \delta\left(u_{i}, a\right) P\left(u^{n}\right)\left[\prod_{r=1,2} P\left(\tilde{e}_{r} \mid e_{r}\right) \delta\left(e_{r}, e_{r}\left(u^{n}\right)\right)\right] \prod_{j} P\left(\tilde{u}_{j} \mid u_{j}\right)  \tag{52.18}\\
& \quad=\mathcal{N}(!a) \lambda_{i}(a) \pi_{i}(a) R \tag{52.19}
\end{align*}
$$

where

$$
\begin{align*}
R & =\sum_{u^{n}} \delta\left(u_{i}, a\right)\left[\prod_{r=1,2} P\left(\tilde{e}_{r} \mid e_{r}\left(u^{n}\right)\right)\right] \prod_{j \neq i} P\left(\tilde{u}_{j} \mid u_{j}\right) P\left(u_{j}\right)  \tag{52.20}\\
& =\sum_{u^{n}} \delta\left(u_{i}, a\right)\left[\prod_{r=1,2} K_{r}\left(u^{n}\right)\right] \prod_{j \neq i} \lambda_{j}\left(u_{j}\right) \pi_{j}\left(u_{j}\right)  \tag{52.21}\\
& =\mathcal{T}_{i}^{K_{1} K_{2}}\left[\prod_{j \neq i} \lambda_{j}\left(u_{j}\right) \pi_{j}\left(u_{j}\right)\right] . \tag{52.22}
\end{align*}
$$

Hence

$$
\begin{equation*}
B E L_{i}(a)=\mathcal{N}(!a) \lambda_{i}(a) \pi_{i}(a) \mathcal{T}_{i}^{K_{1} K_{2}}\left[\prod_{j \neq i} \lambda_{j}\left(u_{j}\right) \pi_{j}\left(u_{j}\right)\right] \tag{52.23}
\end{equation*}
$$

## QED

### 52.1 Decoding Algorithm

The Turbo algorithm for decoding the encode message is as follows. For $m=0$, let

$$
\begin{equation*}
\pi_{j}^{(0)}\left(u_{j}\right)=\frac{1}{n_{\underline{u}_{j}}} \tag{52.24}
\end{equation*}
$$

Then for $m=1,2, \ldots$, let

$$
\begin{equation*}
\pi_{i}^{(m)}=\mathcal{N}_{i} \mathcal{T}_{i}^{K_{m \% 2}}\left[\prod_{j \neq i} \lambda_{j} \pi_{j}^{(m-1)}\right] \tag{52.25}
\end{equation*}
$$

where $m \% 2=1$ if $m$ is odd and $m \% 2=2$ if $m$ is even. Furthermore, for $m>0$, let

$$
\begin{align*}
B E L_{i}^{(m)} & =\mathcal{N}_{i} \lambda_{i} \pi_{i}^{(m-1)} \pi_{i}^{(m)}  \tag{52.26}\\
& =\mathcal{N}_{i} \lambda_{i} \pi_{i}^{(m-1)} \mathcal{T}_{i}^{K_{m \% 2}}\left[\prod_{j \neq i} \lambda_{j} \pi_{j}^{(m-1)}\right] \tag{52.27}
\end{align*}
$$

As $m \rightarrow \infty, B E L_{i}^{(m)}$ given by Eq. 52.27) is expected to converge to the the exact $B E L_{i}$ given by Eq. 52.13).

Turbo decoding can be represented by the bnets Figs 52.3 and 52.4 .
The node TPMs, printed in blue, for Fig 52.3, are given by:

$$
\begin{equation*}
P\left(d_{i}^{(m)}=a \mid \tilde{u}^{n}, \tilde{e}_{m \% 2}\right)=B E L_{i}^{(m)}(a) . \tag{52.28}
\end{equation*}
$$

Figure 52.3: B net describing Turbo code generation of $B E L_{i}^{(m)}(a)$ for $m=1,2, \ldots$.

Figure 52.4: B net describing Turbo code generation of $B E L^{n(m)}(\cdot)$ and $\pi^{n(m)}(\cdot)$ for $m=0,1,2 \ldots$ The following arrows were not drawn so as not to unduly clutter the diagram: Arrows pointing from node $\underline{\lambda}^{n}(\cdot)$ to nodes $\underline{\pi}^{n(m)}(\cdot)$ and $\underline{B E L^{n(m)}}(\cdot)$ for $m=0,1,2, \ldots$.

The TPMs, printed in blue, for Fig. 52.4 , are given by:

$$
\begin{equation*}
P\left(\left(\lambda^{n}\right)^{\prime}(\cdot) \mid \tilde{u}^{n}\right)=\delta\left(\left(\lambda^{n}\right)^{\prime}(\cdot), \lambda^{n}(\cdot)\right) \tag{52.29}
\end{equation*}
$$

$$
\begin{equation*}
P\left(\pi^{n(m)}(\cdot) \mid \lambda^{n}(\cdot), \pi^{n(m-1)}(\cdot), \tilde{e}_{m \% 2}\right)=\prod_{i} \prod_{u_{i}} \delta\left(\pi_{i}^{(m)}\left(u_{i}\right), \mathcal{N}_{i} \mathcal{T}_{i}^{K_{m \% 2}}\left[\prod_{j \neq i} \lambda_{j} \pi_{j}^{(m-1)}\right]\right) \tag{52.30}
\end{equation*}
$$

$$
\begin{equation*}
P\left(B E l^{n(m)}(\cdot) \mid \lambda^{n}(\cdot), \pi^{n(m)}(\cdot), \pi^{n(m-1)}(\cdot)\right)=\prod_{i} \prod_{u_{i}} \delta\left(B E L_{i}\left(u_{i}\right), \mathcal{N}_{i} \lambda_{i} \pi_{i}^{(m-1)} \pi_{i}^{(m)}\right) \tag{52.31}
\end{equation*}
$$

### 52.2 Message Passing Interpretation of Decoding Algorithm

Ref. [17] shows that the Turbo code decoding algo can be interpreted as an application of Message Passing. We leave all talk of Message Passing to a separate chapter, Chapter 31.

## Chapter 53

## Uplift Modelling

This chapter is based on many references, including Ref. [10, 6, 82, 32].
Uphill Modelling (UP) deals with the application of Rubin's Theory of Potential Outcomes (PO) to advertisement and marketing.

PO, which is discussed in Chapter 39, is a subset of Pearl's Causal Inference. Besides UP, other applications of PO theory that are discussed in this book are: Regression Discontinuity (Chapter 42), Difference-in-Differences (Chapter 11) and Synthetic Controls (Chapter 50).

In UP, each participant person is interrogated at two well anticipated, fairly closely spaced times $t_{0}$ and $t_{1}$ (as opposed to Difference-in-Differences (DID), where $t_{0}$ and $t_{1}$ might be years apart, and long before the DID analysis is attempted.). In between those two times, a treatment which we will refer to as the UP diagnostic test is applied. For example, at times $t_{0}$ and $t_{1}$, every participant might be asked how important he/she rates climate change on a scale of 1 to 10 . In between times $t_{0}$ and $t_{1}$, every participant might be sent a brochure on climate change. In UP, as in all other PO applications, each sample $\sigma$ is in the treated or control groups, but not both. But in UP, the same participant can be in both the treated and control groups. If so, that participant is considered two different samples $\sigma$; for example, $\sigma=$ treatedBob, controlBob. In UP, the samples are aware of which of those groups they are in, so they are not "treatment blind". As explained in Chapter 39, strata matching is only valid if the samples of the test are treatment blind. Therefore, the only treatment effect that makes sense for UP is SDO, because it does not require strata matching.

### 53.1 UP types

Let $y_{t}^{B} \in \mathbb{R}$ for $t=t_{0}, t_{1}$ be the treatment response at time $t$ for participant $B$. (We are using here the same notation as in Chapter 39). Call $\delta^{B}=y_{t_{1}}^{B}-y_{t_{0}}^{B}$ the participant uplift for participant $B$. As shown in Fig.53.1, UP classifies participants into 4 UP-types: Persuadables, SureThings, LostCauses, and SleepyDogs. The UP-type of a participant depends on the changes that are induced on that participant by an

Figure 53.1: UP diagnostic test can be used to classify all participants of the population into 4 UP-types. This figure assumes $y \in\{0,1\}$. More generally, $y \in \mathbb{R}$. $t$ represents time. $t=t_{0}$ corresponds to $d=0=$ untreated, and $t=t_{1}$ corresponds to $d=1=$ treated .

## UP-diagnostic-test.

- For a Persuadable participant, $\delta^{B}>0$.
- For a SleepyDogs participant, $\delta^{B}<0$.
- For a SureThings participant, $\delta^{B} \approx 0$ and $y_{t_{0}}^{B}$ is high.
- For a LostCauses participant, $\delta^{B} \approx 0$ and $y_{t_{0}}^{B}$ is low.

Suppose $B$ belongs to stratum $A_{x}$. What is commonly called the uplift is the stratum-uplift $\delta_{x}=S D O$. Strata can also be classified into the 4 UP-types, depending on the sign and size of their $\delta_{x}$. A participant may not be typical for his stratum and may have different participant and stratum UP-types. For example, he may have positive participant uplift and therefore have a Persuadable participant UP-type, but his stratum-uplift might be negative, so he has the SleepyDogs stratum UP-type.

Advertisers are very interested in finding the Persuadable strata in a population so as to focus their resources on them. For example, UP was used very successfully during the Obama presidential campaigns. Team Obama conducted UP-diagnostic tests much like the climate change one described earlier. This allowed them to identify voters who might be sitting on the fence on whether to vote for Obama or not. Then Team Obama spent the lion share of resources on those fence-sitters.

### 53.2 Some Relevant Technical Facts from Chapter 39

Some relevant technical facts about SDO that were proven in Chapter 39 are

- $S D O=0$ is the hypothesis tested by a Randomized Clinical Trial (RTC).
- Using $\underline{y}=\underline{y}(\underline{d})$ and Fig 39.7 , we get

$$
\begin{align*}
S D O & =\sum_{y} y\left[P_{\underline{y}(1) \mid \tilde{d}, \underline{x}}(y \mid 1, x)-P_{\underline{y}(0) \mid \tilde{d}, \underline{x}}(y \mid 0, x)\right]  \tag{53.1}\\
& =\sum_{y} y\left[P_{\underline{y} \mid \tilde{d}, \underline{x}}(y \mid 1, x)-P_{\underline{y} \mid \tilde{d}, \underline{x}}(y \mid 0, x)\right] \tag{53.2}
\end{align*}
$$

If $\underline{y} \in\{0,1\}$, then

$$
\begin{equation*}
\underbrace{S D O}_{\delta_{x}}=\underbrace{P_{y \mid \underline{d}, x}(1 \mid 1, x)}_{Y_{x}^{1}}-\underbrace{P_{y \mid \underline{d}, x, \underline{x}}(1 \mid 0, x)}_{Y_{x}^{0}} . \tag{53.3}
\end{equation*}
$$

- Recall that in Chapter 39, we used $A_{d, x}=\left\{\sigma: \tilde{d}^{\sigma}=d, x^{\sigma}=x\right\}, A_{x}=A_{0, x} \cup A_{1, x}$ and $A=\cup_{x} A_{x}$; also $N_{d, x}=\left|A_{d, x}\right|, N_{x}=\left|A_{x}\right|$ and $N=|A|$. From Eq. 39.87), we get

$$
\begin{equation*}
\underbrace{\widehat{S D O}}_{\delta_{x}}=\underbrace{\frac{1}{N_{1, x}} \sum_{\sigma \in A_{1, x}} y^{\sigma}}_{Y_{x}^{1}}-\underbrace{\frac{1}{N_{0, x}} \sum_{\sigma \in A_{0, x}} y^{\sigma}}_{Y_{x}^{0}} . \tag{53.4}
\end{equation*}
$$

### 53.3 UP Analysis

The input to UP is a PO dataset $D S=\left\{\left(\sigma, d^{\sigma}, x^{\sigma}, y^{\sigma}\right): \sigma=0,1,2, \ldots, n s a m-1\right\}$. where $d^{\sigma} \in\{0,1\}, x^{\sigma} \in S_{\underline{x}}, y^{\sigma} \in \mathbb{R}$. A participant $B$ is assigned two different $\sigma$ if he/she belongs to both the treated and control groups. We will assume $S_{x}$ is a finite set. In general, $x=\left(x_{0}, x_{1}, \ldots, x_{n-1}\right)$ is an $n$ dimensional vector of features $x_{i}$. If any of the $x_{i}$ is a priori continuous, we will assume it has been binned into a finite number of bins.

Starting with $D S$, UP performs the following steps. Fig 53.2 is a pictorial representation of the quantities that are calculated during these steps.

1. Find $A_{x}$ for each observed $x \in S_{\underline{x}}$. Set $A_{x}=\emptyset$ for unobserved $x \in S_{\underline{x}}$.

Figure 53.2: Pictorial representation of the sequence $\left\{\left(\mathcal{X}_{c}, \Delta_{c}\right)\right\}_{c=0,1, \ldots, n c-1}$.
2. Calculate $\delta_{x}$ for each $x \in S_{\underline{x}}$. Set $\delta_{x}=0$ if $A_{x}=\emptyset$.
3. Calculate the set

$$
\begin{equation*}
\left\{\Delta_{c}\right\}_{c=0,1, \ldots, n c-1}=\left\{\delta_{x}: x \in S_{\underline{x}}\right\} \tag{53.5}
\end{equation*}
$$

of distinct uplifts $\delta_{x}$. The class labels $c$ should be assigned so that the sequence of $\Delta_{c}$ is monotonic and non-increasing; i.e.,

$$
\begin{equation*}
\Delta_{0} \geq \Delta_{1} \geq \cdots \geq \Delta_{n c-1} \tag{53.6}
\end{equation*}
$$

Now calculate

$$
\begin{equation*}
\mathcal{X}_{c}=\left\{x: \delta_{x}=\Delta_{c}\right\} \tag{53.7}
\end{equation*}
$$

for each $c$. By the end of this step, we will have calculated $\left\{\left(\mathcal{X}_{c}, \Delta_{c}\right)\right\}_{c=0,1, \ldots, n c-1}$. We will refer to the $\mathcal{X}_{c}$ as strata-bins. Note that

$$
\begin{align*}
\Delta_{c} & =\frac{1}{\left|\mathcal{X}_{c}\right|} \sum_{x \in \mathcal{X}_{c}} \delta_{x}  \tag{53.8}\\
& =\underbrace{\frac{1}{\left|\mathcal{X}_{c}\right|} \sum_{x \in \mathcal{X}_{c}} Y_{x}^{1}}_{Y_{c}^{1}}-\underbrace{\frac{1}{\left|\mathcal{X}_{c}\right|} \sum_{x \in \mathcal{X}_{c}} Y_{x}^{0}}_{Y_{c}^{0}} \tag{53.9}
\end{align*}
$$

4. For each $c$, calculate

$$
\begin{equation*}
\Sigma_{d, c}=\cup_{x \in \mathcal{X}_{c}} A_{d, x} \tag{53.10}
\end{equation*}
$$

for $d \in\{0,1\}$ and

$$
\begin{equation*}
\Sigma_{c}=\Sigma_{0, c} \cup \Sigma_{1, j} \tag{53.11}
\end{equation*}
$$

Figure 53.3: Plot of UP results. Alternative to Qini curves.
Fig 53.3 is a way of plotting the results of UP in an intuitive way that even a business type can understand. UP software often plots something called a Qini curve, but I find Qini curves opaque, confusingly defined in the literature, unnecessary and not very well motivated. So I don't use them.

### 53.4 UP Decision Trees

In this section, we will describe how to build UP decision trees (UP dtrees), and explain why they are needed for UP.

Generic dtrees are described in Chapter 10. This section complements rather than replaces that chapter so the reader is advised to read that chapter first.

Ref.[32] is an excellent paper on the use of dtrees in UP.
The analysis described previously in Section 53.3, although theoretically correct, will work very poorly in practice. The strata-bins of Section 53.3 correspond to the classification classes of a dtree. But strata-bins are very specific so they severely overfit the data. Although dtrees can also suffer from overfitting, there are known methods of preventing or mitigating overfitting in dtrees.

There are also tasks that dtrees can do well and the methods explained so far cannot do well. For example, suppose we have a classless dataset $D S^{-}=\left\{\left(\sigma, x^{\sigma}\right)\right.$ : $\left.\sigma \in \Sigma^{-}\right\}$and we want to predict the class $c^{\sigma}$ and uplift $\Delta_{c^{\sigma}}$ for each of these individuals $\sigma \in \Sigma^{-}$. A dtree can easily do that. The alternative is to use the classy dataset $D S=\left\{\left(\sigma, x^{\sigma}, c^{\sigma}\right): \sigma \in \Sigma\right\}$ to prepare a dictionary that orders the elements of $S_{\underline{x}}$ and gives a class $c$ and an uplift value $\Delta_{c}$ for each feature vector $x \in S_{\underline{x}}$. But such a dictionary overfits and says nothing for feature vectors $x$ that do not show up in the classy dataset $D S$; i.e., the dictionary doesn't guess (interpolate). Dtrees, on the other hand, do guess.

So, without further ado, let us describe how to modify the results of Chapter 10 on generic dtrees to the case of UP dtrees. The main difference, as we will explain in detail next, is that the Information Gain metric used for generic dtrees needs to be replaced by another metric.

$$
\begin{array}{cc}
\left\{N_{j}^{d}(c)\right\}_{c \in S_{\underline{c}}}\left\{N_{k}^{d}(c)\right\}_{c \in S_{\underline{c}}} \\
\sum_{c \in S_{\underline{c}}} N_{j}^{d}(c)=N_{j}^{d} & \sum_{c \in S_{\underline{c}}} N_{k}^{d}(c)=N_{k}^{d} \\
\sum_{k \in c h(j)} N_{k}^{d}(c)=N_{j}^{d}(c)
\end{array}
$$

Figure 53.4: Fig 10.4 with $d$ dependence added. $d \in\{0,1\}$ is the treatment dose.
Fig 53.4 was obtained from Fig 10.4 in Chapter 10 by adding $d$ dependence. $d \in\{0,1\}$ is the treatment dose. Since $d \in\{0,1\}$, in UP, we build two dtrees of the type that were built in Chapter 10 (both with the same structure but with different probabilities associated with each node). $N_{j}^{d}(c)$ is the number of individuals $\sigma$ in the

Figure 53.5: Bnet derived from population numbers in Fig 53.4
population that reaches node $\underline{x}_{j}$ with $d \in\{0,1\}$ and belonging to class $c \in S_{\underline{c}}$. From these population numbers, we can define the bnet in Fig 53.5. The TPMs, printed in blue, for the (non-root) nodes of this bnet, are as follows

$$
\begin{gather*}
P(c \mid k, d)=\frac{N_{k}^{d}(c)}{N_{k}^{d}}  \tag{53.12}\\
P(k \mid j, d)=\frac{N_{k}^{d}}{N_{j}^{d}} \mathbb{1}(k \in \operatorname{ch}(j)) \tag{53.13}
\end{gather*}
$$

In Chapter 10, we used Information Gain (a mutual information) as the SAM (Separation Ability Measure) in SL (Structure Learning) of dtrees (Decision Trees). Information Gain is not an ideal SAM for SL of UP dtrees, because UP trees have a more specialized classification goal than the generic dtrees of Chapter 10. Both UP trees and generic trees want to separate the sample population into classes, but the classes for an UP dtree are specifically uplift bins (i.e., uplift intervals).

Ref. 32] proposes and studies the following 3 SAMs. These SAMs are more efficient than Information Gain for doing SL of UP dtrees.

1. SAM_DD ( $\mathrm{DD}=$ Delta Delta)

For $d \in\{0,1\}$ and $c, c^{\prime} \in S_{\underline{c}}$, define the increments

$$
\begin{equation*}
\partial_{d} f(d)=f(1)-f(0) \tag{53.14}
\end{equation*}
$$

and

$$
\begin{equation*}
\partial_{c^{\prime}, c} f(c)=f\left(c^{\prime}\right)-f(c) . \tag{53.15}
\end{equation*}
$$

Let

$$
\begin{align*}
\Delta_{c \mid j} & =P(c \mid j, 1)-P(c \mid j, 0)  \tag{53.16}\\
& =\partial_{d} P(c \mid j, d) \tag{53.17}
\end{align*}
$$

$$
\begin{align*}
S A M_{-} D D_{j} & =\max _{c, c^{\prime}}\left|\partial_{c^{\prime}, c} \partial_{d} P(c \mid j, d)\right|  \tag{53.18}\\
& =\max _{c, c^{\prime}}\left|\partial_{c^{\prime}, c} \Delta_{c \mid j}\right| \tag{53.19}
\end{align*}
$$

2. SAM_KL (KL=Kullback Liebler)

$$
\begin{align*}
S A M_{-} K L_{j} & =\left[\sum_{k \in c h(j)} P(k \mid j) D_{K L}\left(P_{\underline{c} \mid k, 1} \| P_{\underline{c} \mid k, 0}\right)\right]-D_{K L}\left(P_{\underline{c} \mid j, 1} \| P_{\underline{c} \mid j, 0}\right)  \tag{53.20}\\
& =\left[\sum_{k \in c h(j)} P(k \mid j) \sum_{c \in S_{\underline{\underline{c}}}} P(c \mid k, 1) \ln \frac{P(c \mid k, 1)}{P(c \mid k, 0)}\right]-\sum_{c \in S_{\underline{\underline{c}}}} P(c \mid j, 1) \ln \frac{P(c \mid j, 1)}{P(c \mid j, 0)} \tag{53.21}
\end{align*}
$$

## $S A M_{-} K L_{j}$ can be negative.

3. SAM_E (E=Euclidean)
$S A M_{\_} E_{j}$ is defined the same way as $S A M_{-} K L_{j}$ except with the KL divergence $D_{K L}(P \| Q)$ in $S A M_{-} K L$ replaced by the Euclidean distance squared.

$$
\begin{equation*}
D(P, Q)=\sum_{x}(P(x)-Q(x))^{2} \tag{53.22}
\end{equation*}
$$

The intuitive reason for using these quantities as SAMs is that they maximize the change in uplift between successive tree levels, so that the uplift increases as quickly as possible as we descend down the UP tree. In the case of generic dtrees for which we use Information Gain as SAM, we are maximizing the correlation between classes and nodes as we descend down the tree. These two goals are related. In fact, in the limit where the number of control individuals becomes zero, $S A M_{-} K L_{j}$ and INFO_gain j become the same, as will be shown later.

Next we show that $S A M \_K L_{j}$ satisfies the following 3 axioms ${ }^{1}$

## Claim 30 .

1. $S A M_{-} K L_{j}$ is minimum iff $P(c \mid k, 0)=P(c \mid k, 1)$ for all $c$ and $k \in \operatorname{ch}(j)$.
2. If $P(c \mid j, d)=P(c \mid d)$ for all $c, d$, then $S A M_{-} K L_{j}=0$.
3. Suppose $N_{r}^{0}=0$ for all nodes $r \in J_{0}$ (i.e., no control population) and we use the Laplace Correction when warranted. Then

$$
\begin{align*}
S A M_{-} K L_{j} & =H(\underline{c}: \underline{k} \mid j, 1)  \tag{53.23}\\
& =I N F O_{-} \text {gain }_{j} \quad \text { for treated population } . \tag{53.24}
\end{align*}
$$

[^27]
## proof:

The proof of items 1 and 2 follow by inspection of Eq 53.21 . Item 3 is proven in Claim 31 below. QED

Let $N_{\underline{c}}=\left|S_{\underline{c}}\right|$. Define the uniform probability distribution

$$
\begin{equation*}
U_{\underline{c}}(c)=\frac{1}{N_{\underline{c}}} \tag{53.25}
\end{equation*}
$$

for all $c \in S_{c}$.
Eq. 53.12 for the TPM of node $\underline{c}$ in the bnet Fig 53.5 can be "Laplace Corrected" as follows so that it is no longer undefined when its denominator vanishes:

$$
P(c \mid j, d)= \begin{cases}\frac{N_{j}^{d}(c)}{N_{j}^{d}} & \text { if } N_{j}^{d}>0  \tag{53.26}\\ U_{\underline{c}}(c) & \text { if } N_{j}^{d}=0 \text { (Laplace Correction) }\end{cases}
$$

Claim 31 Suppose $N_{r}^{0}=0$ for all dtree nodes $r \in J_{0}$ and we use the Laplace Correction when warranted. Then

$$
\begin{equation*}
S A M_{-} K L_{j}=H(\underline{c}: \underline{k} \mid j, 1) . \tag{53.27}
\end{equation*}
$$

## proof:

For all nodes $r \in J_{0}$, we must have

$$
\begin{equation*}
P_{\underline{\underline{c}} \mid r, 0}=U_{\underline{\underline{c}}} \tag{53.28}
\end{equation*}
$$

so

$$
\begin{align*}
D_{K L}\left(P_{\underline{c} \mid r, 1} \| P_{\underline{c} \mid r, 0}\right) & =D_{K L}\left(P_{\underline{c} \mid r, 1} \| U_{\underline{c}}\right)  \tag{53.29}\\
& =\ln \left(N_{\underline{c}}\right)-H(\underline{c} \mid r, 1) . \tag{53.30}
\end{align*}
$$

For all $k \in \operatorname{ch}(j)$, we must also have

$$
\begin{equation*}
N_{j}=N_{j}^{1}, N_{k}=N_{k}^{1} \tag{53.31}
\end{equation*}
$$

so

$$
\begin{equation*}
P(k \mid j)=P(k \mid j, 1) . \tag{53.32}
\end{equation*}
$$

Now using Eqs. (53.30) and (53.32), we get

$$
\begin{align*}
S A M_{-} K L_{j} & =-\left[\sum_{k \in c h(j)} P(k \mid j) H(\underline{c} \mid k, 1)\right]+H(\underline{c} \mid j, 1)  \tag{53.33}\\
& =-\left[\sum_{k \in c h(j)} P(k \mid j, 1) H(\underline{c} \mid k, 1)\right]+H(\underline{c} \mid j, 1)  \tag{53.34}\\
& =-H(\underline{c} \mid \underline{k}, j, 1)+H(\underline{c} \mid j, 1) \quad \text { (using Claim } 8)  \tag{53.35}\\
& =H(\underline{c}: \underline{k} \mid j, 1) \tag{53.36}
\end{align*}
$$

## QED

### 53.4.1 Appendix, connection between $\Delta_{c}$ and $\Delta_{c \mid j}$

Recall Eq.53.9:

$$
\begin{align*}
\Delta_{c} & =\underbrace{\frac{1}{\left|\mathcal{X}_{c}\right|} \sum_{x \in \mathcal{X}_{c}} Y_{x}^{1}}_{Y_{c}^{1}}-\underbrace{\frac{1}{\left|\mathcal{X}_{c}\right|} \sum_{x \in \mathcal{X}_{c}} Y_{x}^{0}}_{Y_{c}^{0}}  \tag{53.37}\\
& =\partial_{d} Y_{c}^{d} \tag{53.38}
\end{align*}
$$

Compare that to Eq. (53.17):

$$
\begin{align*}
\Delta_{c \mid j} & =P(c \mid j, 1)-P(c \mid j, 0)  \tag{53.39}\\
& =\partial_{d} P(c \mid j, d) \tag{53.40}
\end{align*}
$$

What is the connection between these 2 deltas, $\Delta_{c}$ and $\Delta_{c \mid j}$ ? Are they equal?
First off, notice that $\Delta_{c \mid j}$ is defined for all nodes $j$ of the dtree. Let $j(c)$ be the leaf node for which $\Delta_{c} \approx \Delta_{c \mid j(c)}$. Assume $y^{\sigma} \in\{0,1\}$. Then

$$
\begin{equation*}
P(c \mid j=j(c), d)=\frac{N_{j(c)}^{d}(c)}{N_{j(c)}^{d}} \approx Y_{c}^{d} \tag{53.41}
\end{equation*}
$$

So the two deltas are indeed approximately equal when $y^{\sigma} \in\{0,1\}$ and $j=j(c)$.

## Chapter 54

## Variational Bayesian Approximation

For more info and references about this topic, see Ref. [83].
The Variational Bayesian approximation (VBA) is an analytic (as opposed to numerical) approximation to the probability distribution $P(h \mid \vec{x})$, where $h$ are the hidden variables and $\vec{x}$ is the data.

More precisely, suppose $\underline{h} \in S_{\underline{h}}$ and $\underline{q} \in S_{\underline{h}}$. Suppose $\underline{\vec{x}} \in S_{\underline{x}}^{\text {nsam }}$ is a vector of $n$ sam samples and the samples $\underline{x}[\sigma] \in S_{\underline{x}}$ are i.i.d.. The VBA is simply an approximation $P_{\underline{q} \underline{\underline{x}}}$ to $P_{\underline{h} \mid \underline{\vec{x}}}$ :

$$
\begin{equation*}
P_{\underline{h} \mid \underline{\vec{x}}}(h \mid \vec{x}) \approx P_{\underline{q} \mid \underline{\vec{x}}}(h \mid \vec{x}) \tag{54.1}
\end{equation*}
$$

obtained by minimizing the Kullback-Liebler divergence $D_{K L}\left(P_{q \mid \underline{x}} \| P_{\underline{h} \mid \underline{x}}\right)$ over all $P_{\underline{q} \mid \vec{x}}$. The minimization is usually subject to some constraints on the admissible forms of $P_{\underline{q} \underline{\underline{\mid}}}$.
$D_{K L}(Q \| P) \neq D_{K L}(P \| Q)$; i.e., $D_{K L}$ is not symmetric. So why do we use $D_{K L}\left(P_{\underline{q} \underline{\underline{\vec{x}}}} \| P_{\underline{h} \underline{\vec{x}}}\right)$ instead of $D_{K L}\left(P_{\underline{h} \underline{\vec{x}}} \| P_{q \underline{\overrightarrow{\vec{x}}})}\right.$ ? Because $D_{K L}\left(P_{\underline{h} \mid \underline{\vec{x}}} \| P_{\underline{q} \underline{\underline{\vec{x}}}}\right)$ requires knowledge of $\bar{P}_{\underline{h} \underline{\vec{x}}}$, but calculating $P_{\underline{h} \mid \underline{\vec{x}}}$ is what we are trying to do in the first place.

Figure 54.1: If $P_{q}(h)$ is Gaussian shaped and $P_{\underline{h}}(h)$ has multiple bumps (modes) then $D_{K L}\left(P_{\underline{q}} \| P_{\underline{h}}\right)$ is minimized when $P_{\underline{q}}$ fits one of the modes of $P_{\underline{h}}$. That is because $D_{K L}\left(P_{\underline{q}} \| P_{\underline{h}}\right)=\sum_{h} P_{\underline{q}}(h) \ln \frac{P_{\underline{q}}(h)}{P_{\underline{\underline{h}}}(h)}$ is a weighted average with weights $P_{\underline{q}}$, so nothing going on outside the support of $P_{\underline{q}}$ influences much the final average.

See Fig 54.1 for some intuition on what minimizing $D_{K L}\left(P_{\underline{q} \underline{\underline{\vec{x}}}} \| P_{\underline{h} \mid \underline{\underline{x}}}\right)$ means.

Figure 54.2: $\underline{q}$ and $\underline{h}$ have $n h=2$ mirroring components and those of $\underline{q}$ are independent at fixed $\underline{\vec{x}}$.

Suppose $\underline{h}=\left(\underline{h}_{0}, \underline{h}_{1}, \ldots, \underline{h}_{n h-1}\right)$ and $\underline{q}=\left(\underline{q}_{0}, \underline{q}_{1}, \ldots, \underline{q}_{n h-1}\right)$ where $\underline{h}_{i} \in S_{\underline{h}_{i}}$ and $\underline{q}_{i} \in S_{\underline{h}_{i}}$ for all $i$. We say $\underline{q}$ and $\underline{h}$ have $n h$ mirroring components and those of $\underline{q}$ are independent at fixed $\underline{\vec{~}}$ if

$$
\begin{equation*}
P_{\underline{q} \mid \overrightarrow{\underline{x}}}(h \mid \vec{x})=\prod_{i} P_{\underline{q}_{i} \mid \overrightarrow{\underline{x}}}\left(h_{i} \mid \vec{x}\right) . \tag{54.2}
\end{equation*}
$$

The bnet Fig 54.2 describes the scenario that we have in mind: The samples $\underline{x}[\sigma]$ are i.i.d.. Each component $\underline{h}_{i}$ of $\underline{h}$ has a mirroring component $\underline{q}_{i}$ in $\underline{q}$. The components of $\underline{h}$ are correlated whereas those of $\underline{q}$ are independent at fixed $\underline{\vec{x}}$.

Claim 32 If $\underline{q}$ and $\underline{h}$ have nh mirroring components and those of $\underline{q}$ are independent at fixed $\underline{\vec{x}}$ and $D_{K L}\left(P_{\underline{q} \mid \underline{\vec{x}}} \| P_{\underline{h} \mid \underline{\vec{x}}}\right)$ is minimum over all $P_{\underline{q} \mid \underline{\vec{x}}}$, then

$$
\begin{align*}
P_{\underline{q}_{i} \mid \overrightarrow{\underline{x}}}\left(q_{i} \mid \vec{x}\right) & =\mathcal{N}\left(!q_{i}\right) e^{\left.E_{\left(\underline{q}_{j}\right)}\right)_{j \neq i}\left[\ln P_{\underline{\underline{\underline{\mid} \mid \underline{\underline{x}}}}}(\underline{h}=q \mid \vec{x})\right]}  \tag{54.3}\\
& =\mathcal{N}\left(!q_{i}\right) e^{\left.E_{\left(\underline{q}_{j}\right)}\right)_{j \neq i}\left[\ln P_{\underline{h}, \overrightarrow{\underline{x}}}(\underline{h}=q, \vec{x})\right]} \tag{54.4}
\end{align*}
$$

for all $i$.

## proof:

Since all quantities in Eq.(54.3) are conditioned on $\vec{x}$, let us omit all mention of $\vec{x}$ in this proof.

Let

$$
\begin{equation*}
\mathcal{L}=\mathcal{L}_{0}+\mathcal{L}_{1} \tag{54.5}
\end{equation*}
$$

where

$$
\begin{align*}
\mathcal{L}_{0} & =D_{K L}\left(P_{\underline{q}} \| P_{\underline{h}}\right)  \tag{54.6}\\
& =\sum_{h} P_{\underline{q}}(h) \ln \frac{P_{\underline{q}}(h)}{P_{\underline{h}}(h)}  \tag{54.7}\\
& =\sum_{h} P_{\underline{q}}(h) \ln P_{\underline{q}}(h)-\sum_{h} P_{\underline{q}}(h) \ln P_{\underline{h}}(h)  \tag{54.8}\\
& =\sum_{i} \sum_{h_{i}} P_{\underline{q}_{i}}\left(h_{i}\right) \ln P_{\underline{q}_{i}}\left(h_{i}\right)-\sum_{h} P_{\underline{q}}(h) \ln P_{\underline{h}}(h) \tag{54.9}
\end{align*}
$$

and

$$
\begin{equation*}
\mathcal{L}_{1}=\sum_{i} \lambda_{i}\left[\sum_{h_{i}} P_{\underline{q}_{i}}\left(h_{i}\right)-1\right] . \tag{54.10}
\end{equation*}
$$

Then

$$
\begin{equation*}
\delta \mathcal{L}=\sum_{i} \sum_{h_{i}} \delta P_{\underline{q}_{i}}\left(h_{i}\right)\left[\ln P_{\underline{q}_{i}}\left(h_{i}\right)+1+\lambda_{i}-\frac{1}{n h} \sum_{\left(h_{j}\right)_{j \neq i}} \prod_{\left(h_{j}\right)_{j \neq i}}\left\{P_{\underline{q}_{j}}\left(h_{j}\right)\right\} \ln P_{\underline{h}}(h)\right] . \tag{54.11}
\end{equation*}
$$

Hence,

$$
\begin{equation*}
P_{\underline{q}_{i}}\left(h_{i}\right)=\mathcal{N}\left(!h_{i}\right) e^{\sum_{\left(h_{j}\right)_{j \neq i}}\left\{\Pi_{\left(h_{j}\right)_{j \neq i}} P_{q_{j}}\left(h_{j}\right)\right\} \ln P_{\underline{h}}(h)} \tag{54.12}
\end{equation*}
$$

## QED

Note that Eq. (54.3) yields a system of $n h$ nonlinear equations in $n h$ unknowns $\left(P_{\underline{q}_{i} \mid \overrightarrow{\underline{\underline{x}}}}\right)_{i=0,1, \ldots, n h-1}$. This system is usually solved recursively.

### 54.1 Free Energy $\mathcal{F}(\vec{x})$

To simplify the notation below, let us introduce the following abbreviations:

$$
\begin{gather*}
P(h \mid \vec{x})=P_{\underline{h} \mid \underline{\vec{x}}}(h \mid \vec{x})  \tag{54.13}\\
P(h, \vec{x})=P_{\underline{h}, \overrightarrow{\vec{x}}}(h, \vec{x})  \tag{54.14}\\
P(\vec{x})=P_{\underline{\vec{x}}}(\vec{x}) \tag{54.15}
\end{gather*}
$$

Note that

$$
\begin{align*}
D_{K L}\left(P_{\underline{q} \mid \overrightarrow{\underline{x}}} \| P_{\underline{h} \mid \underline{\vec{x}}}\right) & =\sum_{h} P_{\underline{q} \mid \underline{\vec{x}}}(h \mid \vec{x}) \ln \frac{P_{q \underline{\underline{\vec{x}}}}(h \mid \vec{x})}{P(h \mid \vec{x})}  \tag{54.16}\\
& =\sum_{h} P_{\underline{q} \mid \underline{\vec{x}}}(h \mid \vec{x}) \ln \frac{P_{q \underline{\underline{\vec{x}}}}(h \mid \vec{x})}{P(h, \vec{x})}+\ln P(\vec{x})  \tag{54.17}\\
& =\mathcal{F}(\vec{x})+\ln P(\vec{x}) \tag{54.18}
\end{align*}
$$

Hence, the Free energy $\mathcal{F}(\vec{x})$ is defined as

$$
\begin{align*}
\mathcal{F}(\vec{x}) & =\sum_{h} P_{\underline{q} \mid \overrightarrow{\vec{x}}}(h \mid \vec{x}) \ln \frac{P_{\underline{q} \mid \overrightarrow{\underline{x}}}(h \mid \vec{x})}{P(h, \vec{x})}  \tag{54.19}\\
& =E_{\underline{q} \mid \underline{\underline{x}}}\left[\ln \frac{P_{\underline{q} \mid \overrightarrow{\vec{x}}}(q \mid \vec{x})}{P_{\underline{h}, \overrightarrow{\underline{x}}}(q, \vec{x})}\right] . \tag{54.20}
\end{align*}
$$

The name free energy is justified because

$$
\begin{equation*}
\mathcal{F}(\vec{x})=\underbrace{-\sum_{h} P_{\underline{q} \mid \overrightarrow{\vec{x}}}(h \mid \vec{x}) \ln P_{\underline{h}, \overrightarrow{\vec{x}}}(h, \vec{x})}_{U, \text { Internal Energy }}+\underbrace{\sum_{h} P_{\underline{q} \mid \overrightarrow{\vec{x}}}(h \mid \vec{x}) \ln P_{\underline{q} \mid \underline{\vec{x}}}(h \mid \vec{x})}_{-S, \text { minus Entropy }} . \tag{54.21}
\end{equation*}
$$

It is also common to define a quantity called "ELBO" to be the negative of the free energy.

$$
\begin{equation*}
E L B O(\vec{x})=-\mathcal{F}(\vec{x}) \tag{54.22}
\end{equation*}
$$

ELBO stands for "Evidence Lower BOund". That name is justified because

$$
\begin{equation*}
\underbrace{\ln P_{\underline{\vec{x}}}(\vec{x})}_{\text {evidence } \leq 0}=\underbrace{D_{K L}\left(P_{\underline{q} \mid \vec{x}} \| P_{\underline{h} \mid \underline{\vec{x}}}\right)}_{\geq 0}-|E L B O(\vec{x})| . \tag{54.23}
\end{equation*}
$$

Some properties of $\mathcal{F}$ are:

- $\mathcal{F}$ is non-negative.

$$
\begin{equation*}
\underbrace{D_{K L}\left(P_{\underline{q} \mid \underline{\underline{x}}} \| P_{\underline{h} \mid \underline{\underline{x}}}\right)}_{\geq 0}+\underbrace{\ln \frac{1}{\left.P_{\overrightarrow{\vec{x}}}(\vec{x})\right]}}_{\geq 0}=\mathcal{F}(\vec{x}) \tag{54.24}
\end{equation*}
$$

- KL divergence is min iff $\mathcal{F}$ is min at fixed $P(\vec{x})$.

Figure 54.3: $D_{K L}+\ln \frac{1}{P(\vec{x})}=\mathcal{F}$.

During a variation $\delta$ that holds $P(\vec{x})$ fixed, the KL divergence and $\mathcal{F}$ change by the same amount:

$$
\begin{equation*}
\delta D_{K L}\left(P_{\underline{q} \mid \underline{\vec{x}}} \| P_{\underline{h} \mid \underline{\vec{x}}}\right)=\delta \mathcal{F}(\vec{x}) \tag{54.25}
\end{equation*}
$$

## Chapter 55

## Zero Information Transmission (Graphoid Axioms)

This chapter assumes that you have read Chapter 14 on d-separation.
The following quantities play a very prominent role in the d-separation Theorem that we enunciated in Chapter 14 .

- the mutual information (MI)
(aka information transmission) $H(\underline{a}: \underline{b})$
- the conditional mutual information (CMI)
(aka conditional information transmission) $H(\underline{a}: \underline{b} \mid \underline{c})$
MI can be viewed as the special case of CMI, when the set of variables being conditioned on is empty. Particularly prominent in d-separation discussions are probability distributions for which CMI vanishes. The goal of this chapter is to study such probability distributions.

Recall that CMI is non-negative and symmetric in its first two variables (i.e., $H(\underline{a}: \underline{b} \mid \underline{c})=H(\underline{b}: \underline{a} \mid \underline{c}))$. Another very useful property of CMI is its chain rule (easy to prove from the definition of CMI):

$$
\begin{equation*}
H\left(\underline{y}: \underline{x}^{n}\right)=\sum_{i} H\left(\underline{y}: \underline{x}_{i} \mid \underline{x}_{<i}\right), \tag{55.1}
\end{equation*}
$$

where $\underline{x}^{n}=\left(\underline{x}_{0}, \underline{x}_{1}, \ldots, \underline{x}_{n-1}\right)$ and $\underline{x}_{<i}=\left(\underline{x}_{0}, \underline{x}_{1}, \ldots, \underline{x}_{i-1}\right)$.
A trivial but very useful consequence of the chain rule for CMI is:

$$
\begin{equation*}
H\left(\underline{y}: \underline{x}^{n}\right)=0 \Longleftrightarrow H\left(\underline{y}: \underline{x}_{i} \mid \underline{x}_{<i}\right)=0 \text { for all } i \tag{55.2}
\end{equation*}
$$

### 55.1 Consequences of Eq. (55.2)

Table 55.1 gives a set of statements about CMI referred to as the Graphoid Axioms in chapter 1 of Ref.[26]. See Ref.[26] to learn the history of these axioms. The purpose
of this section is to prove that the graphoid axioms are all a simple consequence of Eq. 55.2.

| Symmetry | $\underline{a} \perp_{P} \underline{b} \Longrightarrow \underline{b} \perp_{P} \underline{a}$ |
| :--- | :--- |
| $H(\underline{a}: \underline{b})=0 \Longrightarrow H(\underline{b}: \underline{a})=0$ |  |
| Decomposition | $\underline{a} \perp_{P} \underline{b}, \underline{c} \Longrightarrow \underline{a} \perp_{P} \underline{b}$ and $\underline{a} \perp_{P} \underline{c}$ |
|  | $H(\underline{a}: \underline{b}, \underline{c})=0 \Longrightarrow H(\underline{a}: \underline{b})=0$ and $H(\underline{a}: \underline{c})=0$ |
| Weak Union | $\underline{a} \perp_{P} \underline{b}, \underline{c} \Longrightarrow \underline{a} \perp_{P} \underline{b} \mid \underline{c}$ and $\underline{a} \perp_{P} \underline{c} \mid \underline{b}$ |
|  | $H(\underline{a}: \underline{b}, \underline{c})=0 \Longrightarrow H(\underline{a}: \underline{b} \mid \underline{c})=0$ and $H(\underline{a}: \underline{c} \mid \underline{b})=0$ |
| Contraction | $\underline{a} \perp_{P} \underline{\underline{b}} \mid \underline{c}$ and $\underline{a} \perp_{P} \underline{c} \Longrightarrow \underline{a} \perp_{P} \underline{b}, \underline{c}$ |
| $H(\underline{a}: \underline{b} \mid \underline{c})=0$ and $H(\underline{a}: \underline{c})=0 \Longrightarrow H(\underline{a}: \underline{b}, \underline{c})=0$ |  |
| Intersection | $\underline{a} \perp_{P} \underline{b} \mid \underline{c}, \underline{d}$ and $\underline{a} \perp_{P} \underline{d}\left\|\underline{c}, \underline{a} \Longrightarrow \underline{a} \perp_{P} \underline{b}, \underline{d}\right\| \underline{c}$ |
| $H(\underline{a}: \underline{b} \mid \underline{c}, \underline{d})=0$ and $H(\underline{a}: \underline{c} \mid \underline{c}, \underline{b})=0 \Longrightarrow H(\underline{a}: \underline{b}, \underline{d} \mid \underline{c})=0$ |  |

Table 55.1: Graphoid Axioms

Claim 33 Table 55.1 is true.
proof:

- Symmetry

Follows trivially from $H(\underline{a}: \underline{b})=H(\underline{b}: \underline{a})$.

## - Decomposition

From the chain rule for CMI, we have

$$
\begin{equation*}
H(\underline{a}: \underline{b}, \underline{c})=H(\underline{a}: \underline{b} \mid \underline{c})+H(\underline{a}: \underline{c}), \tag{55.3}
\end{equation*}
$$

and

$$
\begin{equation*}
H(\underline{a}: \underline{b}, \underline{c})=H(\underline{a}: \underline{c} \mid \underline{b})+H(\underline{a}: \underline{b}) . \tag{55.4}
\end{equation*}
$$

Hence,

$$
\begin{equation*}
H(\underline{a}: \underline{b}, \underline{c})=0 \tag{55.5}
\end{equation*}
$$

implies

$$
\begin{equation*}
H(\underline{a}: \underline{b} \mid \underline{c})=H(\underline{a}: \underline{c})=0, \tag{55.6}
\end{equation*}
$$

and

$$
\begin{equation*}
H(\underline{a}: \underline{c} \mid \underline{b})=H(\underline{a}: \underline{b})=0 . \tag{55.7}
\end{equation*}
$$

## - Weak Union

Already proven in proof of Decomposition.

## - Contraction

From chain rule for CMI, we have

$$
\begin{equation*}
H(\underline{a}: \underline{b}, \underline{c})=H(\underline{a}: \underline{b} \mid \underline{c})+H(\underline{a}: \underline{c}) . \tag{55.8}
\end{equation*}
$$

## - Intersection

From the chain rule for CMI, we have

$$
\begin{equation*}
H(\underline{a}: \underline{b}, \underline{d} \mid \underline{c})=H(\underline{a}: \underline{b} \mid \underline{d}, \underline{c})+H(\underline{a}: \underline{d} \mid \underline{c}), \tag{55.9}
\end{equation*}
$$

and

$$
\begin{equation*}
H(\underline{a}: \underline{b}, \underline{d} \mid \underline{c})=H(\underline{a}: \underline{d} \mid \underline{b}, \underline{c})+H(\underline{a}: \underline{b} \mid \underline{c}) . \tag{55.10}
\end{equation*}
$$

Thus,

$$
\begin{equation*}
H(\underline{a}: \underline{b}, \underline{d} \mid \underline{c})=0 \tag{55.11}
\end{equation*}
$$

implies

$$
\begin{equation*}
H(\underline{a}: \underline{b} \mid \underline{d}, \underline{c})=H(\underline{a}: \underline{d} \mid \underline{c})=0, \tag{55.12}
\end{equation*}
$$

and

$$
\begin{equation*}
H(\underline{a}: \underline{d} \mid \underline{b}, \underline{c})=H(\underline{a}: \underline{b} \mid \underline{c})=0 . \tag{55.13}
\end{equation*}
$$

[84] Hao Wu and Zhaohui Steve Qin. course notes, BIOS731: Advanced statistical computing, 2016 Emory Univ. http://web1.sph.emory.edu/users/hwu30/ teaching/statcomp/statcomp.html.

[^0]:    ${ }^{2}$ Note the difference between $\vee$ and modulus 2 addition $\oplus$. For $\oplus($ aka XOR): $x \oplus y=x+y-2 x y$.

[^1]:    ${ }^{3} \mathrm{CMI}$ can be read as "see me".

[^2]:    ${ }^{4}$ The uniqueness of a CC bnet can be taken to be an implicit axiom of causality theory. Alternatively, instead of assuming uniqueness, one can assume that out of all CC bnets that fit the data well, one can find the "best" one. Here the definition of "best" is not unique and depends on a non-unique figure of merit defined in terms of Pearl do interventions.
    ${ }^{5}$ We won't use the term "causal bnet" in this book. Pearl defines a causal bnet to be a CC bnet that is also a "SCM" (i.e., a bnet whose internal nodes are deterministic and external ones are probabilistic.)

[^3]:    ${ }^{1}$ Mnemonic for remembering order of indices: $i$ in numerator $/ j$ in denominator becomes index $i / j$ of Jacobian matrix.

[^4]:    ${ }^{1}$ Kruskal's algorithm is one several famous algorithms (Prim's algo is another one) for finding an MST (maximum or minimum spanning tree). An MST algorithm takes an undirected graph with weights along its edges as input. It then finds a tree subgraph (i.e., subset of the edges of the graph with no loops) that (1) spans the graph (i.e., includes every vertex of the graph) and (2) maximizes (or minimizes) the sum of weights among all possible tree subgraphs. For more information, see $\operatorname{Ref}[68$ and references therein, or any other of numerous explanations of MST in the Internet.

[^5]:    ${ }^{1}$ The question-answer pairs in dtrees are often also referred to as attribute-value pairs.

[^6]:    ${ }^{2}$ SAM is also called, somewhat confusingly, the splitting criterion and Gain.

[^7]:    ${ }^{1}$ ATT stands for the average treatment effect of the treated. ATT is defined in Chapter 39

[^8]:    ${ }^{1}$ As usual, $\mathcal{N}(!x)$ denotes a constant that is independent of $x$.

[^9]:    ${ }^{1} \underline{Z}$. are the nodes we are "conditioning on". Unmeasured (i.e., hidden, unobserved) nodes cannot be conditioned on, because that would entail measuring them.

[^10]:    ${ }^{2}$ Note that $\left(\underline{A} . \perp_{G} n d e(\underline{A}) \mid. p a(\underline{A}).\right)$ and $\left(\underline{A} . \perp_{G} n d e(\underline{A})-.p a(\underline{A}) \mid. p a(\underline{A}).\right)$ are equivalent because $H(\underline{a}: \underline{b}, \underline{c} \mid \underline{c})=H(\underline{a}: \underline{b} \underline{c})$.

[^11]:    ${ }^{1}$ The term "unknown parameter" is mainly of frequentist origin. For Bayesians, $\theta$ is a random variable with a delta function prior, whereas for frequentists, it is not a random variable at all, just an unknown parameter with no randomness.

[^12]:    ${ }^{2}$ Note that that the right hand side of Eq. 16.5 is expressible in the form $\sum_{\sigma} \sum_{h[\sigma]} f(x[\sigma], h[\sigma])$.

[^13]:    ${ }^{1}$ As explained lucidly in Ref.[1], besides detailed balance, 2 other properties must also be satisfied by the Markov chain, irreducibiity and aperiodicity. However, because of how it is constructed, the Metropolis-Hastings algorithm automatically produces a Markov chain that has those 2 properties.

[^14]:    ${ }^{1}$ The pattern behind these definitions, in case it eludes you, is as follows: the $\pi$ 's always carry information about the past and the $\lambda$ 's about the future. But the past or future of what? Of the argument of the function. Out of the two random variables in the subscript of the function, the one on the right hand side of the subscript, the one which is adjacent but beneath the argument, is always the argument.
    ${ }^{2}$ As usual in this book, $\mathcal{N}(!x)$ means a constant that is independent of $x$.

[^15]:    ${ }^{3}$ The term dynamic bnet was used in Chapter 15 to mean a time inhomogeneous Markov chain, but here we are stretching its meaning to include Markov chains that aren't time inhomogeneous.

[^16]:    ${ }^{4}$ Careful: Chapter 4 of Ref. 25 uses - indicate the future and + to indicate the past. This is the opposite of our notation.

[^17]:    ${ }^{5}$ Note that we are using $f_{\alpha}$ to denote both a function $f_{\alpha}(\cdot)$ and a boolean value. Which one we mean will be clear from context. $f_{\alpha}$ could also be used to denote, besides a function and a boolean value, the real number $y_{\alpha}=f_{\alpha}\left(x_{n b\left(\underline{f}_{\alpha}\right)}\right)$. However, we won't be using it that third way in this chapter.

[^18]:    ${ }^{6}$ By "recursive nature", we mean bootstraped definitions that lead to nested sums. The recursive nature of BP is evident from RULES 1 and 2 that define $\lambda$ 's and $\pi$ 's in terms of other $\lambda$ 's and $\pi$ 's.

[^19]:    ${ }^{1}$ Normally, if we had changed from the original node names to the $\underline{\tau}_{j}$ node names, these orthogonality relations would first be stated in terms of the $\underline{\tau}_{j}$ names, and we could translate them so that they were stated in terms of the original node names. But for DAG (a) there was no need to use the $\underline{\tau}_{j}$ names.
    ${ }^{2}$ The $\underline{x}_{j}$ node names are no longer in topological order for DAGs $(b)$ and $(c)$ so for them you should go through the intermediate step of renaming the nodes $\underline{\tau}_{j}$, and then, after obtaining the orthogonality relations in terms of the $\underline{\tau}_{j}$ names, translating them back to the original $\underline{x}_{j}$ names.

[^20]:    ${ }^{1}$ The term $\mathbf{A} / \mathbf{B}$ test is often used to mean a RCT where A anb B are the treated and control groups. However, sometimes the term is used to refer to an experiment that conditions on confounders, which violates the definition of a RCT, and is the same as a PO test.

[^21]:    ${ }^{2}$ Note that effects in which $\tilde{d}$ varies are called "controlled", whereas those in which $d$ varies instead, are called simply "treatments". $y$ is averaged over in both cases.

[^22]:    ${ }^{3}$ Careful: We define $A T E_{\mid x}=A T T_{\mid x} P_{\underline{d} \mid \underline{x}}(1 \mid x)+A T U_{\mid x} P_{\underline{d} \mid \underline{x}}(0 \mid x)$. Therefore, $A T E_{\mid x} \neq$ $A T T_{\mid x} P_{\underline{d}}(1)+A T U_{\mid x} P_{\underline{d}}(0)$.

[^23]:    ${ }^{4}$ One can use an $\epsilon$ that depends on $\sigma$. Let $\epsilon(\sigma, 5)$ be the radius necessary so that $\mathcal{M}_{\epsilon(\sigma, 5)}(\sigma)$ contains exactly 5 elements $s$. Thus, $\mathcal{M}_{\epsilon(\sigma, 5)}(\sigma)$ contains the $s$ of the 5 points $x^{s}$ that are the nearest neighbors of $x^{\sigma}$ in the $\operatorname{dist}()$ metric.

[^24]:    ${ }^{5}$ The sigmoid function is defined in Chapter Notational Conventions and Preliminaries to be $\operatorname{sig}(x)=1 /\left(1-e^{-x}\right)$.

[^25]:    ${ }^{1}$ In the popular educational literature, the edge variables $T E F_{i \rightarrow j}$ and $T L F_{i \rightarrow j}$ are sometimes associated with the nodes, but they are clearly edge variables. This makes things confusing. The reason this is done is that some software draws PERT diagrams as trees whereas other software draws them as DAGs. For trees, storing $T E F_{i \rightarrow j}$ and $T L F_{i \rightarrow j}$ in a node makes some sense but not for DAGs. You will notice that giving specific names to the variables $T E F_{i \rightarrow j}$ and $T L F_{i \rightarrow j}$ is unnecessary. It is possible to delete all mention of their names from this chapter without losing any details. I only declare their names in this chapter so as tell the reader what they are in case he/she hears them mentioned and wonders what they are equal to in our notation.

[^26]:    ${ }^{1}$ ATE, which stands for "average treatment effect", is defined in Chapter 39 .

[^27]:    ${ }^{1}$ We won't show it here, but according to Ref. 32], $S A M_{-} E_{j}$ also satifies these 3 axioms, but $S A M_{-} D D_{j}$ satisfies only the first two.
